Better Results from your FORD

MASTER VIBRATOR

CONNECTICUT

$9

Everybody knows that a well disciplined team of horses working together make much easier work of a heavy pull than a team of nervous, fretful horses, no two of which settle down to steady pulling at the same time.

The Coils on your Ford act much the same. Once out of adjustment their erratic timing causes irregular explosions and your motor loses power.

The Connecticut Master Vibrator for Ford cars is a masterpiece of coil construction which not only insures a hot fat spark for each explosion but which times the sparks for all four cylinders of your motor with absolute accuracy.

Price $9.00 at all good dealers or direct from our factory.

The Connecticut Telephone & Electric Company

MERIDEN, CONN.

RAJAH GIANT

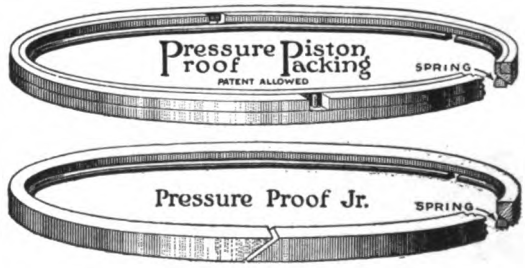
300% in One Year!

That is the increase in the sales of the Rajah Giant Plug

This Plug was originally designed for racing purposes, but its widening popularity for general use on motor boats, tractors, trucks and pleasure cars has necessitated its addition to our regular line.

In construction, with the exception that it is much heavier in the porcelain and metal parts, it is the same as the

RAJAH "STANDARD" PLUG



Extremely simple for cleaning: — only four parts—shell, porcelain, bushing and gasket. All standard threads.

Rajah Giant Plug $1.50
Rajah Standard Plug 1.25 } Postpaid—with Thumb-nut Terminal

Dealers: If you haven't carried Rajah Plugs in stock, did you ever stop to think how many sales you may have lost? Many thousands of car owners use no other plug. **Write us for particulars.**

RAJAH AUTO-SUPPLY CO.

BLOOMFIELD NEW JERSEY

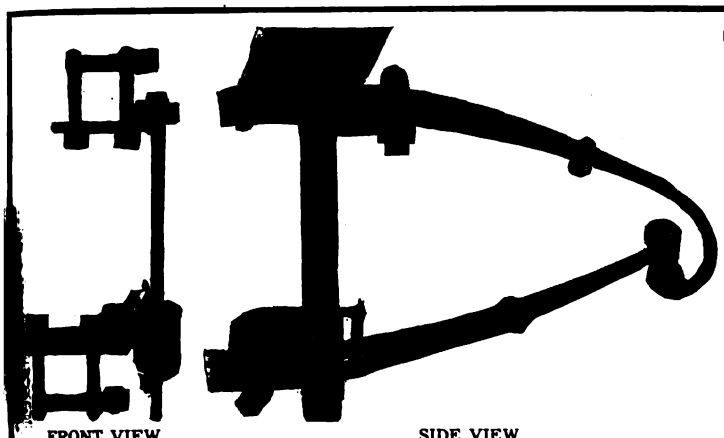
(PATENT APPLIED FOR)

A NEW PRINCIPLE IN PISTON RINGS

One of the principal causes of leakage in piston rings is wear in the ring grooves, and poor fitting at the start. The pressure proof Ring and the Pressure Proof Junior Ring are the only piston rings on the market that automatically adjust themselves to the width of the ring groove, and maintain a tight joint at this point at all times.

Of what avail is a piston ring, however tight in the joints, if it soon wears loose in the groove, and allows pressure and oil to leak under. Pressure proof Piston Rings not only fit automatically, but they maintain a fit as long as they are in service.

Pressure Proof Piston Rings are guaranteed to restore power to worn cylinders that are not scored.



In use on automobiles, motor boats, Stationary engines, air compressors, etc. No danger of breaking or distorting in applying, as Pressure Proof Piston Rings are not stretched over piston in applying.

For full information, write

PRESSURE PROOF PISTON RING CO.

3368 Washington St. Jamaica Plain, Boston, Mass.

FRONT VIEW SIDE VIEW

THE car springs with the shock absorber attached are like a compound bow and arrow of great power. When the springs rebound there is a brake on the arrow or rod of the shock absorber, resulting in an easy upward movement. The shock absorber will outlast the car.

Simpler, more reliable than any other, requires no care. Money back guarantee. They are cheaper than car repairs, wear and tear, besides the ease of riding.

FORD SPECIALTIES

No. 86 FORD COUPELET LAMP AND LICENSE BRACKET.

ALSO FITS OTHER CARS.

Specially designed for the FORD COUPELET and RUNABOUT.

Fastens by same bolts that hold present bracket.

Carries lamp and license plate well above the rear deck clear of mud and dust, permitting your danger light to be plainly seen by "The man behind."

"Safety First—Always."

Throws light directly across license plate. Made of malleable iron, black finish.

List Price $2.00 Each.

FORD LOCK TIRE HOLDER No. 88-9.

Protect Your Tires From Theft.

Carries casings flat, preventing them from sagging out of shape.

Consists of three properly designed light weight brackets, two of which are supplied with straps, the third with a pressed steel swing strap and an all brass automatic Yale Lock which securely locks casing, preventing theft.

Price, $2.50 Complete.

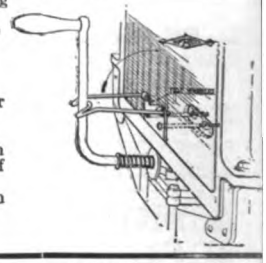
DASH VENTILATOR FOR FORD CARS. No. 240

Makes Driving A Comfort in the Hottest Weather.

Allows comfort to occupants of front seat, by carrying away excessive motor heat from the feet.

The only dash ventilator in the market for FORD CARS which can be used in rainy weather (just when ventilation is most needed, when car is all curtained in) without admitting rain into the car. Easily attached. Nothing to get out of order. Made of pressed steel. Two finishes. Copper Oxidized **$2.00** per pair, Gun Metal **$1.75** per pair, complete.

COMBINATION CRANK HOLDER AND NUMBER BRACKET FOR FORD CARS No. 80.



A practical device for holding crank handle in upright position, protecting it from road obstructions and mud. Much quicker and neater than the old way of holding by crank strap. Stops rattle and dangling of crank, thus saving wear. Hard Rubber Finish.

Easy to attach by same nuts that hold front spring clips. Positively locks back against radiator, allowing spinning of motor without danger of engaging with crank handle. **50c Complete.**

FORD CRANK HOLDER.

No. 85.

Holds crank handle in upright position clear of road obstruction.

Stops wear and rattle.

Positively snaps back against radiator, which permits spinning motor without danger of striking holder.

Better, Quicker and more Serviceable than crank straps.

Price, 25c.

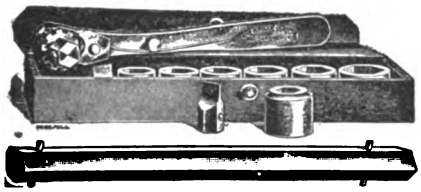
"UFASCO" ADJUSTABLE OIL CAN HOLDER. No. 60.

You Don't Know What A Necessity It Is Until You Have Used Our No. 60.

You cannot afford to be without one.

None better. Positive Grip.

Adjustable to all sizes of 3⅜", 3¾", and 4½" oil cans. Holds can tight, preventing rattle. Fasten either with or without bracket.



Saves time, oil and money by always being "where you can find it."

Has most flexible action and gripping quality of any holder on the market.

List Price, 25c. Each.

Agents Wanted

The Most Perfect Piston Rings Made

PERFECTION PISTON RINGS

They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.

This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.

PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

Western Representatives North and South: West of Denver

A SAVING OF 25% ABSOLUTELY GUARANTEED

In any and all kinds of weather on your GASOLINE in using our

CARBURETTE VAPORIZER

FOR FORD CARS

Start your engine and smell of the exhaust—you will notice a decided odor of gasoline. This means you are not getting the use of all the gasoline which goes into your motor.

This wasted gasoline amounts to fully 33⅓% and is due to the fact that your mixture is not properly vaporized in your carburetor.

Cold Gasoline Will Not Give Off A Vapor

The Carburette Vaporizer is attached to the exhaust pipe with a simple clamp. Here the heat from the exhaus. is utilized to BOIL the GASOLINE. The hot gasoline enters the carburetor and on coming in contact with the air INSTANTLY VAPORIZES.

This is not a new principle but a tried fact. Boiling gasoline is constantly used by the big racers in the middle of summer.

By compelling this absolute vaporization your gasoline consumption will be from 25 to 50% less (our own comparative test shows 50%), not only this but you get

INCREASED POWER REDUCED CARBON
INSTANT ACCELERATION

The Carburette Vaporizer is a positive filter, now a recognized necessity in these days of low grade gasoline. We have provided drain cocks so that sediment and impurities boiled out may be drained off.

PRICE ONLY $2.50

And if not satisfied money refunded

Simple, not complicated, any owner can install in one-half hour. Order from your dealer or through us. Sent C. O. D.

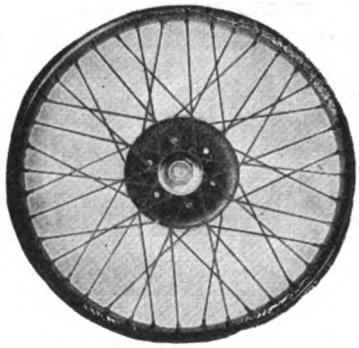
WE MANUFACTURE WRENCHES ONLY

Soak Up the Bumps with the FORDEZER

Registered U. S. Patent Office



For improved riding qualities for which they are responsible are little short of wonderful. Their rapid action permits them to absorb—soak up—the vibration that makes long continued riding tiresome even over city pavements. On rough roads the improvement is even more noticeable. The springs are given a chance to act natural—the snappy recoil which is even worse than the downward bump, is entirely eliminated. The saving it effects in tire expense and car depreciation will more than repay their cost in a season.

Made To Fit All FORD Models

Either Touring or Roadster. They are easily applied. Their construction is the best of any Shock Absorber on the market—absolutely dust-proof; entire mechanism covered with a one-piece drawn shell cover, press fitted to the base. Once a year oiling is all that is required for average use. They will outsell and outwear any other Shock Absorber because all supporting parts are drop forged steel and all moving parts bushed with bronze bearings. The flat section, Vanadium Steel springs are guaranteed for life.

Price per set of four . . . $12.00

Manufactured by
WALKER-MOORE MFG. CO.

Sell your trade a Spare Spring
Ready for Instant Use

Springs with the center bolt usually break in the middle—unless it's a Tuthill Titanic that has no center bolt and is guaranteed for life against center breakage.

And when a tire "blows" it's much easier to get another one than it is to get a spring, even if the motorist does not carry a spare tire.

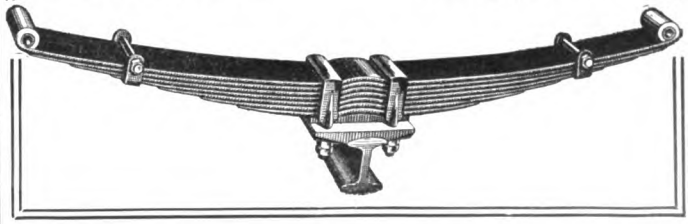
When a spring breaks, however, the motorist is right up against it—perhaps miles away from a repair shop or a garage—so why not sell your trade a Spare Front Spring—and if it's an Unbreakable Titanic his troubles are over.

In addition, we can furnish promptly the Tuthill Titanic equipped with the famous DANN INSERT—the interleaf shock absorber.

Tuthill Titanic Unbreakable Spring

Guaranteed forever against center breakage

Write us today



The Tuthill Titanic is the most satisfactory spring you can sell—it has no center bolt and is guaranteed forever against center breakage.

Most all jobbers carry a complete stock—or we can ship most orders in one day—special orders in 48 hours.

Write today for our special offer on "Best Sellers."

Tuthill "Titanics" can be easily adapted to any axle construction and quickly mounted **without any extra expense.**

Oxy-Acetylene Welding pays Big Profits to Garage Owners

If you are not equipped to do Oxy-Acetylene repairs in your own shop, you're losing good, legitimate profits. With the welding process, you can save money for yourself by cutting repair costs. You avoid unpleasant delays, waiting for replacements. Immediate repairs make pleased patrons. Damaged parts are quickly and easily made good as new at small cost. Most of these repairs would be impossible with any other method. Even at the most moderate charges, the profits from this end of your business are too big to be neglected.

The daily use of the welding equipment requires that it be simple, efficient, portable and economical in operation. We can furnish, at low cost, a thoroughly high-grade welding apparatus for $60.00. The average user will also need gas cylinders, which are extra, and about $10.00 worth of welding supplies. Truck and special equipment for cutting operations at extra cost.

If you use Acetylene for ANY purpose, you can secure added efficiency and wider scope of operations possible, by using.

PREST-O-LITE

Dissolved Acetylene

(Ready-made carbide gas)

Prest-O-Lite Acetylene Service furnishes the highest grade of Dissolved Acetylene in portable cylinders, used as conveniently as you use cylinders of oxygen. Saves the large initial outlay and heavy depreciation, trouble and inconvenience of making crude Acetylene in carbide generators. Besides, Prest-O-Lite Dissolved Acetylene is perfectly dried, cleaned and purified—makes better welds and is cheaper to use.

A Good Business Opportunity

Doing Oxy-Acetylene welding for others is a highly profitable business. The cost of equipment needed is slight. Immense and growing demand assures profitable operation right at the start.

Get Your Share of Welding Profits

Send your name and address immediately for highly instructive literature on Oxy-Acetylene Welding and Cutting. See what others have done—how you can add to your profits by adding the up-to-date methods in your shop.

The Prest-O-Lite Co., Inc., 820 Speedway Indianapolis, Ind.

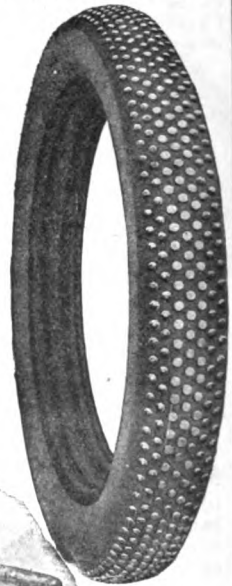
STOP!-THROWING MONEY AWAY ON TIRES

Don't Throw Away Your Worn Tires Like So Much Junk

It is unnecessary, highly extravagant, and altogether uncalled for. **Retread them at a LOW COST with "Pacific Fibre Treads" and cut down your tire expense $50 to $500 a year.** Our Free Booklet tells you how.

In 15 Minutes Old Tires Can be Made Good For



5,000 Miles More

Guaranteed Puncture Proof

Blow-out-Proof; Skid-Proof; Rut-cut-Proof; Rim-cut-Proof; Oil-Proof; Gasoline-Proof; Tear-Proof; Road-Proof; Trouble-Proof.

Special Discount

Offered to motorists in new territory on first shipment direct from factory.

"Pacific Treads"

Are Not Leather Treads

Leather Treads, processed, treated, or tanned as many times as you can imagine, will stretch and sag and being non-resilient can never resume their original shape again with the tire.

Pacific Treads on the other hand fit your tire like a glove and expand or contract evenly, smoothly and instantly—as little or as much as is required—never any more.

We Ship on Approval, Pay the Express and Take All the Risks

Pacific Treads will save every motorist who uses them time, worry, and expense. We will prove it to you at our own expense if you will fill out the coupon below. Mail it today.

Fill Out and Mail NOW

V. K. STURGES, Oakland, Calif.

Look for the name LEAK-PROOF stamped on the Ring

I want some LEAK-PROOF Piston Rings---have you them?

Salesman—Yes, sir—here they are.

Customer—But these are not LEAK-PROOF Piston Rings.

Salesman—Yes, sir—they are leak proof—they claim to stop the leaks.

Customer—But they're not the genuine LEAK-PROOF Piston Rings.

Salesman—That's what we bought them for—leak proof piston rings.

Customer—Then either you've been deceived or are trying to deceive me.

Salesman—What is the difference between those you want and these—aren't they all more or less alike?

Customer—Only in their claims—*not in results.*

Salesman—Are they made differently?

Customer—Yes, decidedly—the construction is absolutely different—it is the construction that makes the genuine LEAK-PROOF Rings efficient—that actually gives more power, maximum compression and minimum carbonization, that maintains perfect bearing on the cylinder walls and retains elasticity.

Salesman—What is it that does all this?

Customer—Two-piece—angle to angle, interlocking construction with the opening in each half of the ring sealed by the other half. If the ring is not a two-piece ring of this special, patented angle to angle, interlocking style of construction the ring is an inefficient imitation.

Salesman—Well—we haven't that kind of ring; can't I sell you the others?

Customer—No—when I buy rings to produce results I want sure results—I have used LEAK-PROOF Rings and gotten results—I don't want to experiment. Good-bye.

You—Mr. Motor Owner—follow his example. As a further aid and protection to you LEAK-PROOF is stamped in this specially designed and registered style of lettering—LEAK-PROOF on every genuine LEAK-PROOF Piston Ring—all others are imitations.

"Ask the User"

Made in All Sizes

Easily Adjusted

Angle to angle interlocking construction identifies LEAK-PROOF—insist.

In use on over 300,000 Motors

Send for FREE Book—"To Have and to Hold Power"

It explains the theory and function of piston rings. It tells about the LEAK-PROOF Ring and why every motor should be equipped with them. How it will pay you in fuel economy and prolonged motor life. Write for it.

Sold by all up-to-date supply houses, garages and repair shops

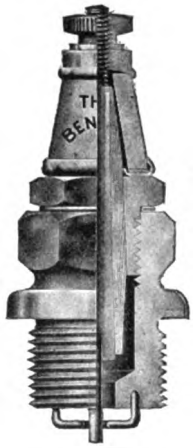
6-T



There's no leak proof ring but the LEAK-PROOF Ring — insist

Send for and read your copy

When your engine balks on the road and the plugs act mysteriously, sometimes all right, sometimes all wrong, when you know carbon is **not** present, but some plug obstinately persists in missing—when a plug sparks if taken out into the open but fails to spark in the motor—do you know exactly how to go after and remedy the trouble? **You would** if you had read this booklet.

Mail the coupon today for your copy, read it carefully, and if some inferior plugs have been "wished upon" you by a dealer who looked more to his own profits than your comforts, pay particular attention to the description of

BENTON CASE-HARDENED SPARK PLUGS

Price $1.00 each

You would like their indestructible, wound mica insulation, gas-tightness, provision for easy and effective cleaning, protection of wrench and thread surfaces from battering, the long-lived and reliable electrodes, etc. Once tried, you will thank us for calling Benton Plugs to your attention.

Dealers: The **real** satisfaction from Benton Plugs stimulates additional trade from your customers, and honestly earns their good-will. Why not investigate our liberal sales proposition and try a few of these plugs where you can observe their performance?

UNITED PRODUCTS MFG. CO.
219 EAST 22nd STREET Dept. A CHICAGO, ILL.

GASOLETTE

Increases the efficiency of Gasoline without injury to motors.

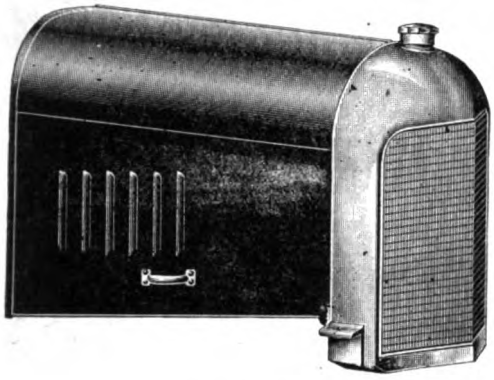
Gives the motor greater pulling power, more speed and 100 per cent flexibility. sparks quicker and helps the engine to almost instantly pick up and to run smoother.

Prevents pre-ignition, pounding and over-heating of engine.

Removes and prevents carbon deposits on spark plugs, pistons, cylinders and valves, and thereby eliminates engine troubles.

Prevents carbon deposits on exhaust valves and seats, thus eliminating cutting and pitting, and consequent loss of power that can be remedied only by grinding valves.

Prevents carbon deposits on intake valves and seats, which deposits cause loss of compression, loss of power and back firing in intake pipe.



Prevents carbon deposits on pistons, gumming and sticking of piston rings, loss of compression, loss of power—and you avoid the trouble and expense of taking down the engine to clean.

Lessens smoke, odor and noise.

Leaves cylinder and valves in an oily condition and therefore adds life to the engine.

MAKE $250.00 A MONTH
REPAIRING AUTOMOBILE TIRES

Sounds like a lot of money—IT IS—A WHOLE LOT of MONEY to be earning CLEAR every month—yet it's what hundreds of men we have established in the Automobile Tire Repair Business are making. You let down the DRAWBRIDGE for SUCCESS to enter into your career by getting into business for yourself. The business for you is one where the investment is small—the returns quick and for cash—where the margin of profit is large—the demand for your PRODUCT or SERVICE constant and ever on the increase.

A HAYWOOD TIRE REPAIR EQUIPMENT

answers to all of these requirements of Old Dame Fortune—the certainty of success in this business is as sure as anything in this world can be—Each year adds thousands of new Automobile Owners—they need YOU to keep their tires in service.

HERE IS YOUR OPPORTUNITY!

Be first to enter this new, big paying business in your town. Open your pockets. Let the dollars pour in. Act quick. Every auto sold means more tires to mend. Automobile business is growing fast—enormous field for tire repairing. Punctures and blowouts are common. Tires need retreading and vulcanizing. Something going wrong all the time. Thousands forced to buy new tires because they can't get old ones fixed. Think of the old bicycle days—repair shops on every corner—all making money—busy day and night. Autos make same proposition over again—only ten times bigger and better. Users of Haywood Tire Repair Plants are making big money. Johnson, Tex., writes: **"I have made as high as $18 in a day."** Another man who bought a plant September, 1911, writes he has **cleared over $3000.00.** That's going some! Operate a plant as a side line in connection with auto business—garage, or as an independent business. Find neighborhood where there's a bunch of autos—get all the steady business besides transient work. Experience unnecessary. You learn quick. Simply follow directions—practice a few days on a couple of old tires and you'll be ready to coin money. Business comes fast and easy.

THIS MAN IS MAKING MONEY

Repair Tires at Home!

Young men and boys! repair father's tires—get money he pays garage man. Get the neighbor's work. Make money to attend college or to start a garage and repair business. **Auto owners**—repair your own tires—save money—pay for your outfit in short time. We have outfits for home use. Anyhow, investigate. Send today for catalogue. See the wonderful possibilities in this marvelous field. Learn of the enormous money-making opportunities in this fascinating new business.

The New Money-Making Business—Start Now.

SPRINGFIELD, OHIO

FOUNTAIN AUTOMOBILE WASHER

SAVES ½ THE TIME

REQUIRED IN WASHING CARS BY OTHER MEANS

Used in up-to-date garages for cleaning cars. It is attached to a special nozzle which permits the flow of water being regulated from a spray to a straight, hard stream which carries the dirt away. A cloth, or even a sponge, rubs the grit in. Washes thoroughly, without soap, in half the time. Well made, durable, no loose bristles, won't scratch varnish. You need this and some of the other special auto brushes and dusters we make.

Brush complete---China Bristle, - $2.00
With extra Palmyra Fibre Brush, $2.50

JOSEPH DIXON CRUCIBLE COMPANY

Established 1827 C-17

For Leaky Cylinders
Superior to All Others

PATENTED AUGUST 6, 1912

A Piston Ring Which Gives Compression in "Out-of-Round" Cylinders as Perfectly as in True Ones

Beware the "Just as Good"

Here is a piston ring that gives 100% efficiency to every type of motor, engine, compressor or pump.

Ideally adapted to use in Automobile and Motorboat engines.

Gives compression when all others fail. No need to rebore worn cylinders—simply install EVER-TIGHT piston rings and the motor is good as new.

EVER-TIGHT piston rings are made up of three individual, interlocking rings, grooved together to give flexibility and reduce friction. This three-part construction is clearly seen in illustrations above. This is the only three-piece piston ring on the market.

If dealers do not carry EVER-TIGHT piston rings, Auto repair men should write us.

Jobbers and dealers wanted everywhere. *Write for particulars.*

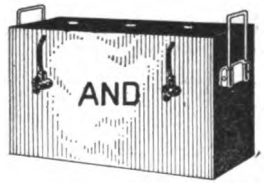
(Where Quality Counts)

Stop the Blinding Headlight Glare!



Chaney Automobile HEADLIGHT DIMMER

It enables the driver to graduate the intensity of the light. It can be changed from high to low as you would turn down an oil lamp. Operated by moving the dimmer handle, it gives complete control of the headlights from the seat. In city driving the light is kept low with small current consumption—in the country where full power is needed a touch of the handle brings back the full searchlight efficiency.

Liven Up Your Motor

New or old, it delivers at best less than 75% of the power you pay for. *New or old,* it leaks gas—wastes power—wastes oil.

New or old, you can improve your motor—make it give more power, use less gas, less oil. We guarantee this absolutely—if you equip your motor with

BURD High Compression Piston Rings

Burd Rings are the only 98% efficient rings. They hold Compression no other rings can touch. There's nothing fancy about Burd Rings—no complicated series of interlapping parts. They're just plain, honest, old-fashioned piston rings, accurately made—the kind all engineers endorse. Only Burd Rings have the opening *guarded*—guarded so it can't leak. That's why they hold higher compression—save gas—save oil—give more power. And Burd Rings do the work. They make your motor buck up. They give you power you are paying for, but aren't getting. They save their cost in a few weeks. They are the only Piston Rings guaranteed to do this.

More Miles Per Gallon

"Since installing Burd Rings, my machine gets away quicker, is 50% better on hills, and I must say I get at least 25% more mileage on same amount of gas, and I have watched this carefully."

P. C. Christman.

Reduces Carbonizing

"Since putting in Burd Rings, my car uses 60% less oil. During 9000 miles with your rings I have had no trouble with carbon and have never removed a spark plug."

John E. Tuttle.

One-third More Power

"Since putting in Burd Rings, my car has at least one-third more power, and we find that we are saving about 10% on our fuel bill."

C. H. Ross.

WARRANTY

We warrant every motor equipped with Burd High Compression Piston Rings to produce Higher Compression and give More Power, using Less Fuel and Oil, than when equipped with any other piston ring made, and we will refund the full purchase price of Burd Rings if after 30 Days' Actual Service they fail to meet this warranty. This warranty does not apply to motors having scored cylinders, until after they are reground.

Send for Valuable Book on

"The Why of a Piston Ring."

If you want your motor to give more power, to run on less gas, you ought to have this book. It fully describes Burd High Compression Piston Rings, quotes prices, gives you lots of information you'll be glad to get. Write a postal for it *now*. Book will come free. Address nearest office.

MOTOR EYE

DETECTS MOTOR TROUBLE INSTANTLY

Flashes a warning of danger before the harm has been done. The motor is the car's most costly piece of mechanism and should be given protection commensurate with its importance. A ruined motor means a ruined car. $2.50 invested in prevention may save $100 expended in repair bills.

A radiator thermometer is the only known means for instantly detecting trouble beneath the hood of a running car.

READY TO ATTACH

$2.50

MOTOR-EYE is the cheapest motor insurance obtainable. Don't pay more for devices that won't do more.

Pin a money order to the attached coupon and get one of these little sentries out on your radiator cap keeping a never-tiring eye on what is going on inside. Money refunded if not satisfied.

Patents Pending

5,000 MILES GUARANTEED

FORD CARS 6,000

With its many layers made of rubber and rubberized canvas impregnated with tread stock in such a way that each layer is woven to the other with rubber and afterwards vulcanized, which makes a stronger and more serviceable tread than the all-rubber tread heretofore used. These layers will not separate, peel off, crack, split, or chunks come out, like the all-rubber tread by the constant vibration. All of these layers are non-skid, but yet a smooth tread, and each layer as they wear off becomes a non-skid and so on until the entire tread is worn out. It takes more than 1,500 miles to wear off one layer. Count the number of non-skid layers and you will see that this tread is good for more than 10,000 miles. It is a tougher tread and more serviceable than heretofore used in other makes of tires. It is the only non-skid tire all the way through ever made, no chains are necessary. It is what is known as a fast tire and takes less engine power and 25 per cent less gasoline. It is free from punctures, stone bruises and never gives any trouble. Try one of these tires with any other tire, which will quickly convince anyone. We only use the most expensive material that goes to make up a tire. If you paid us a $1,000 for a tire, we could not make a better one, because better material is not made. This tire is backed up by the highest percentage of mileage guarantee. Don't buy any tires until you have examined this tire.

Send for booklet telling many other features and agent's proposition.

MANUFACTURED IN U. S. A. BY
OLD SOL
LIGHTING SYSTEMS
HAWTHORNE MFG. CO. BRIDGEPORT, CONN.

OLD SOL Spotlights

THE OLD SOL Spotlight, placed conveniently so that it can be turned at any angle front, back and sideways—is an added comfort and safety in automobiling.

The OLD SOL No. 75 model is admirably adapted for use on Ford and other light cars. No. 70 makes a handsome addition to the equipment of any automobile. Can be quickly detached and used as a trouble light.

The OLD SOL Marine Searchlight is to the motor boat the same relative importance as is the searchlight to the battleship. Equipped with port and starboard signals. Dealers tell us there is a constantly increasing demand. Models No. 70 and No. 75 also adapted for marine service by addition of deck base support for bracket, $1.00 extra.

MARINE Searchlamp

Useful for picking up the buoy, docking, telegraphing (there is a regular code) and for hundreds of other uses where a Safety First Lamp is wanted.

The OLD SOL Pencil Flashlight is more than a pleasing novelty. Every man, no matter what his vocation, should have one. For detectives, reporters, doctors, nurses, they are indispensable.

OLD SOL Pencil Flashlights are selling by the thousands. Ask your dealer.

Sold by Hardware, Electrical, Drug and Novelty Merchants.

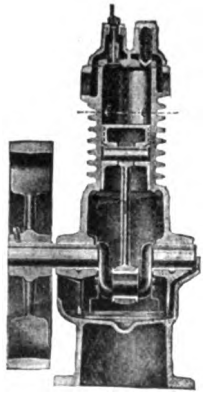
WHICH

OF THESE TWO SIGNS WILL BRING YOU THE MOST CUSTOMERS

THIS OR THIS



You don't hesitate—YOU KNOW—that by giving your customers AIR FREE FROM OIL you increase their tire mileage and decrease their tire expense, but do you know that the

CURTIS GARAGE AIR COMPRESSOR

is the only automatically lubricated garage air compressor that will furnish AIR FREE FROM OIL and won't flood the cylinders with oil.

The oil that will run most compressors 10 hours will run a CURTIS 100 hours. That is only one of many such good features. Each CURTIS is regularly equipped with a device that permits starting up with pressure in the tank with no more power than if the tank were empty. THEN THE COOLING SYSTEM—note the fan fly-wheel. Note the die cast bearings, the controlled splash oiling.

NOTE THE OILING FEATURE

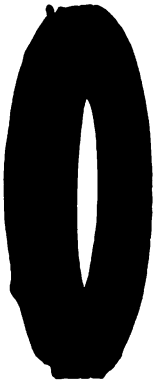
National Rubber Tire Filler

THE ONLY GENUINE ALL RUBBER TIRE FILLER

It is made of the best grade of rubber, cut in small particles molded to a pattern, properly vulcanized by a special process, laid inside the tire and put on with the same pressure as required by air. No chemicals, oils, glucose, or gelatine to damage your tires; nothing but high-grade Rubber. No limit to its life and wearing qualities. Can be changed from one tire to another as often as is necessary. A perfect substitute for air. Rides just as easy after 30,000 miles as when new. From both a business and pleasure standpoint it is the greatest economical factor ever produced.



WRITE AT ONCE FOR FULL PARTICULARS AND SAMPLE

National Rubber Filler Company
208 College Street **Midlothian, Texas**

The Foundation of this Tire

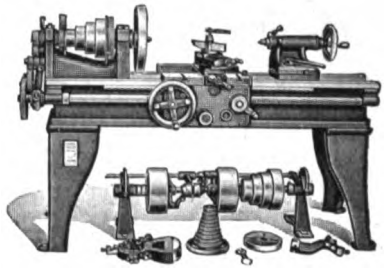
is just as good as the day it was bought. Any tire with good fabric, whether there is any rubber on the outside or not, is suitable for the

TRIPLE TREAD PROCESS

The Triple Tread is the only tire protector made

that does not depend on inflation, rim pressure or mechanical means to hold it in place, so that the style of bead on your tires cannot affect the success of their treatment.

In Vulcanizing the Triple Tread on your Tire



we are able to fill the pores of the leather with rubber, making it waterproof, so that by bringing the leather down the sides and over the bead of the case, covering it completely, we are able to keep dirt and water from getting under the tread to rot the fabric, and also to strengthen the sides and bead of the tire.

Write for our booklet,

"Worn Out Tires Made New."

Please mention the size of your tires.

TRIPLE TREAD MFG. CO.
1542 MICHIGAN AVENUE **CHICAGO**
Factories: San Francisco, Chicago, Winnipeg

The Lathe for Your Shop

YOU should pick the lathe you install in your garage or repair shop with care; know it represents full value for the price you pay; be certain that it is designed right; that it is constructed of approved materials; and last, but by no means least, be sure that the dealer who sells you your lathe is reliable and will do as he agrees.

We claim that our line of Expert Lathes meets all of the above requirements. In addition, we claim that ours are sold under a stronger and more comprehensive guarantee of satisfaction than any other lathes on the market. And our prices are low—$63.00 and up. If you plan to install a lathe in your shop you should get our Machinery Catalog. Write for it today—It's free. Ask for Catalog No. 57A211.

Sears, Roebuck and Co., Chicago

The unique "Porcupine" drive on the

ENGINE PRICES DOWN ANOTHER NOTCH!

Look at these Prices!

2 H-P, $34.95; 4 H-P, $69.75;
6 H-P, $97.75; 8 H-P, $139.65; 12 H-P, $197.00.
Other sizes up to 22 H-P, proportionally low.

Direct from Factory to User!

Why pay two prices for any good engine, or take chances on a poor, or an unknown engine, when the "WITTE" costs so little, and saves you all the risk.

WITTE ENGINES, Kerosene, Gasoline & Gas

LET ME send you a "WITTE" engine to earn its own cost while you pay for it. It's cheaper than doing without one. I have proved that to thousands who are now WITTE users.
Ed. H. Witte.

Stationary, Portable and Saw-rig Styles.

Liberal 5-Year Guaranty CASH OR EASY TERMS.

GET your engine from an engine specialist. All my life I have done nothing but make engines. **The success of my customers and nothing else, makes my success.** I've simply got to sell better engines. I can't lose money on an engine and make back the loss on something else. My factory is the only one, that started in the engine business 28 years ago, which has come through successfully under the same management with which it started. Only WITTE engine-quality has made that possible.

It is cheaper and easier to own a "WITTE" engine than to do without one. My New Offer makes it easier to get the work done by machinery than by muscle or brute power. No need now to get along without a "WITTE."

New Book Free My New Book—the finest in the whole engine business—explains all. It tells you how to be sure in your selection, even if you don't pick a "WITTE." Send me your address today, so I can send you this book FREE with my New Offer.

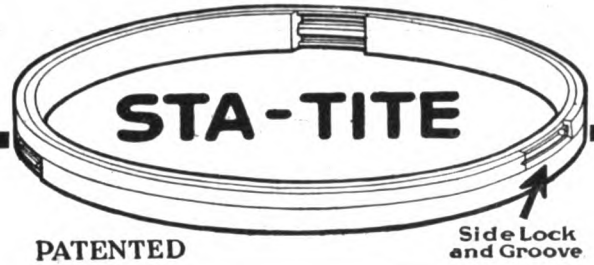
WHY Sta-Tite Piston Rings Are Superior

The STA-TITE PISTON RING is made in three pieces. The "vents" or slot openings provide the spring and resiliency which allows the ring to exert a uniform pressure outwards from its center against the cylinder walls at every point in its circumference. Multiple contact and even distribution of expansion is assured. Leakage is a mechanical impossibility.



"Perfect Compression is the Foundation of Motor Efficiency."
Efficiency Ed.

This cross section shows the STA-TITE patented feature—the inter-locking groove construction. This allows the ring to seat perfectly in the piston groove, thus eliminating "Play" and all possibilities of "carbon pockets."

Under stress of expansion—the joints are held firmly and securely. They cannot overlap and score the cylinder walls.

MANUFACTURED BY THE
STA-TITE PACKING RING CO.
3037 OLIVE STREET ST. LOUIS, MO.

A NEW FORD CAR
EQUIPPED WITH A
PEDERSEN LUBRICATOR

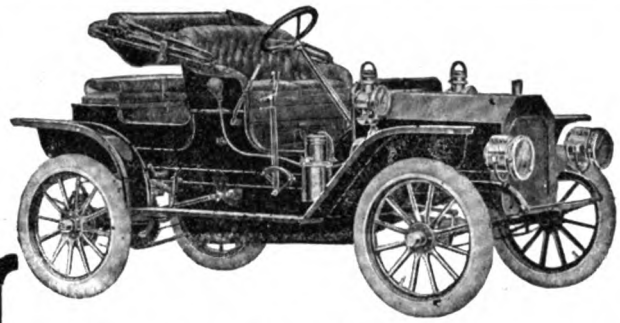
WAS RUN OVER 6000 MILES WITHOUT REGULATION.
Fill the Oil Tank and the Lubricator Does the Rest.

FOR FORD CARS $7.50

This lubricator is positive, entirely mechanical in its working and not depending on gravity and pressure. It has no belts, cams or levers to become deranged, but is attached direct to the engine, *starting and stopping with the motor.*

It insures proper lubrication of the motor, with longer life, smoother running, more power and fewer repair bills. It has a half-gallon oil tank, and allows the car to be driven for hundreds of miles with one filling of the tank.

Applied to the car by anyone in 15 minutes.



THE "UNITED TERMINALS"

as illustrated in above cut are the greatest convenience and trouble saver for Ford users. They bring all the wires on top, easy to get at, preventing them from getting oil soaked, twisted or strained at their connections. Should be on every Ford car.

Easily Applied ***Price 50c.***

Dealers write us, you can make money in handling these goods.

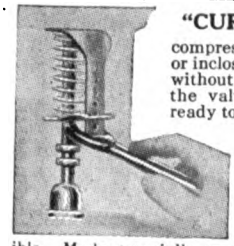
WONDER-MIST

Cleans and Polishes

It removes dust and stains and restores the original lustre to any polished surface.

It contains neither acid, gum nor any other injurious substance.

It preserves and protects the finish.



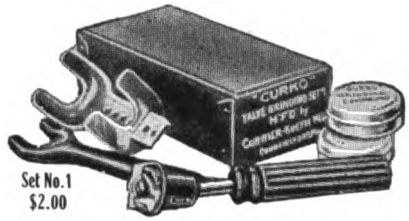
Applied with sprayer, which deposits the liquid in a fine mist evenly. Then polish with a cheesecloth. It is extensively used in Public Garages and by Automobile Owners. A trial makes a constant user.

If your dealer cannot supply you, send us his name.

The Wonder-Mist Co., 14 Federal St., Boston, Mass.

CURKO Motor Valve Tools

Are simple, practical and accurate tools no autoist or garage man should be without. Valves repaired in half the time and work, with a better job the result.



"CURKO" Valve Remover

compresses any valve spring on open or inclosed type valve spring motors, without removing manifold. Holds the valve spring compressed until ready to be replaced. **Price 75c.**

"CURKO" Ford Socket Wrench

not "stamped," but turned from solid nickel steel bars, broached and case hardened, practically indestructible. Made especially to meet the needs of the autoist and garage man. Five socket sizes. In waterproof roll. Price $1.50 per set.

"CURKO" Valve Grinding Set

Set No. 1 includes our fast grinding, non-gumming and non-magnetic compound—two grades—one for truing the seat, the other for fine finishing; one "CURKO" Valve Remover and one "CURKO" Valve Grinder.
Price $2.00 complete.

Also **"CURKO" Valve Reseating Grinders,** hand power, foot power and belt driven styles.
Folder and prices on request.

"CURKO" Guarantee Against any defects of workmanship or material in "Curko" Motor Valve Tools.

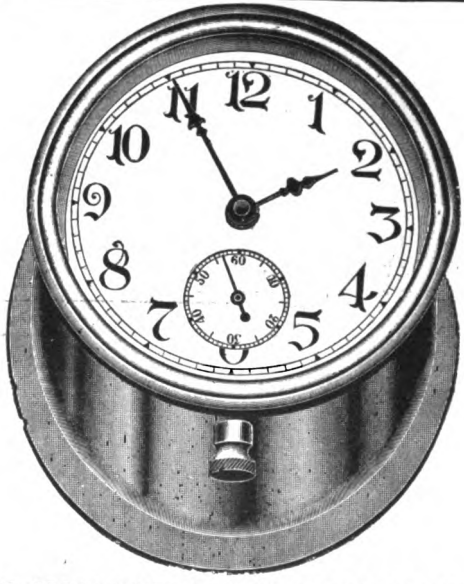
Every Repair Shop or Garage SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock** 38½ inches high, with a 12 inch dial, finished in **Oak** or **hand-rubbed Mahogany**, with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper.

Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.

The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.



Remittances can be made in any convenient way. Be sure to state whether you want this clock in Oak or Hand-Rubbed Mahogany.

Address all orders to

DO YOU WANT A MOTOR CLOCK

For your car, and a good one? The clock illustrated in this connection is manufactured by one of the most reliable clock companies in the country and is warranted in every respect. It is not liable to get out of order. It has interchangeable parts. It is the product of skilled labor combined with the most improved Waltham Automatic Machines. This clock is 3¾ inches high, and has a Porcelain dial 2½ inches in diameter. It has a one day movement with second hand. It can be furnished in burnished brass or nickel plated whichever is preferred. The arrangement we have made enables us to furnish **one of these clocks and a subscription to the Automobile Dealer and Repairer for a year** to all residents of the United States and its territories for the precise price the clock retails for, namely, **$2.50.** If an eight day clock is preferred send 50 cents extra or $3.00. Canadian subscribers should add 50 cents extra to cover the extra postage required on the **Automobile Dealer and Repairer.** This clock cannot be sent to foreign countries. The clock can safely be sent by mail and will be forwarded postage prepaid to any part of the country. Remittances can be made in any convenient way. Address

GET THEM NOW!

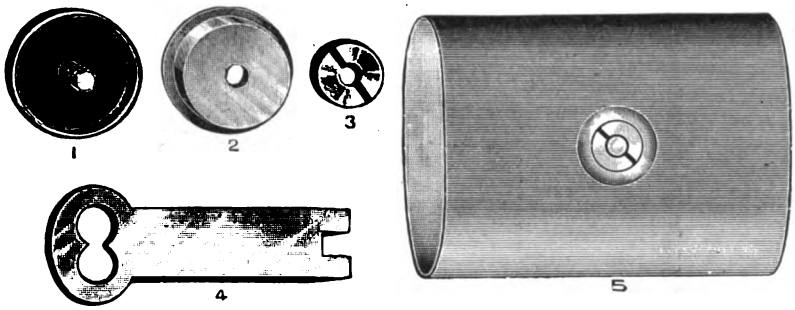
The Old Way

More power, better acceleration, greater mileage per gallon and less carbon trouble—you can have all these by adding

SU-DIG SERIES PLUGS

to the plugs you now have. Get them now, of your dealer or from us, and have the benefit of them all this season.

Interesting booklet free.



Dealers—SU-DIG Plugs mean extra sales and profits Write us today.

Superior Motor Specialty Co., 40 N. 4th St., Philadelphia

The SU-DIG Way

One Minute Answer to Flat Tires

¶ An inexperienced person can make a permanent repair on an inner tube in ONE MINUTE.
¶ Plug will repair any hole smaller than itself.
¶ Unlike any other inner tube repair—they can be used over and over again.
¶ Cheapest and best repair that can be made on an inner tube.
¶ GUARANTEED not to Chafe nor Cut the TUBE or FABRIC.
¶ Automatically vulcanize themselves to the inner tube and cannot leak.
¶ The saving in expense for repairing punctures in inner tubes by the use of Spitler Puncture Plugs is a conservative economy that will appeal to all motorists.
¶ PRICE of 1-inch size, $1.00 for set of 4 Plugs and one wrench mounted on heavy cardboard and each set put up in a neat box.

SPITLER PUNCTURE PLUGS ECLIPSE ALL OTHER INNER TUBE REPAIRS. LIVE AGENTS WANTED. WRITE TODAY.

B. W. SPITLER, - - - - 52 Clayburne St., Dorchester, Mass.

Gouin's Anti-Rattler For Auto Doors

Car Owners Have Long Been Looking for this Device———

Can be applied by anyone in a few minutes, and instantly puts a tension on your door so that rattling is absolutely impossible. They act the same way on the hoods and keep them from rattling. Simply rivet under hood ledge and radiator ledge.

HARRIS

TRADE MARK REG. U.S. PAT. OFF.

OILS AND GREASES

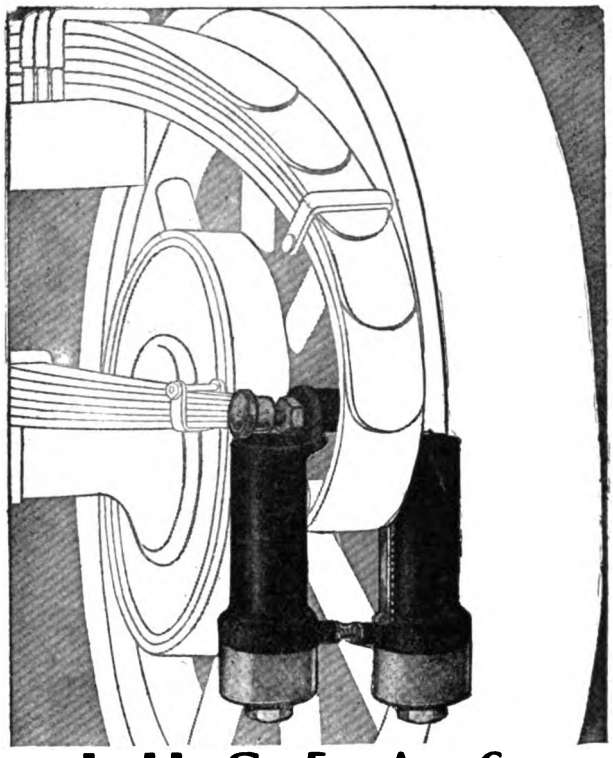
DOES SHE SMOKE?

Well, she ought not to. No matter whether she is old or young, your car can be properly lubricated. Smoke means that your lubricant is being wasted—that carbon is depositing on piston heads and valves.

You will find, by using pure HARRIS OILS, that the smoke nuisance can be eliminated. That is one of the reasons why so many dealers recommend them.

Sold in Barrels, Half-Barrels, 10 Gallon, 5 Gallon and 1 Gallon Cans.

"A Little Goes A Long Way and Every Drop Counts."



A. W. HARRIS OIL CO.,

326 S. Water St., Providence, R. I.

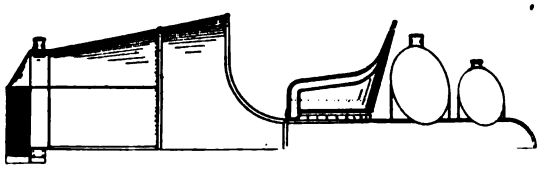
REPAIRMEN! MAKE MONEY REBORING CYLINDERS

Pat. 1091318. May 19th, '14.
HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES

This tool accomplishes results the same as grinders costing several hundred dollars and a few jobs enables the machine to pay for itself, besides giving the customer service which it would be impossible to give otherwise.

It requires an expenditure of $6.00, and 90 minutes energy to make the cylinders and pistons as tight, true and new as the day they left the Ford Factory. Reboring and fitting oversize pistons is the most important repair that can be given a worn motor, and this is the most important tool you can buy for your shop, for the low price of the tool together with the low price of the pistons makes it an attractive proposition for the repairman who wants to make his shop popular.



Do it now: The first job of reboring means $ $ $ $ $ to you, if it is done in your shop.

Write for Full Particulars and Proposition

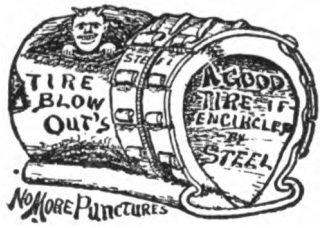
We furnish the oversize pistons, $1.50 each, net.

HEISER SPECIAL TOOL CO. - - - Kingston, Missouri

CHANGE YOUR FORD CAR INTO A SPEEDSTER

You can make this change yourself. Install one of our V-shaped radiators, tapered hood, roadster seats, oil and gasoline tanks. We furnish trunk tool-box in place of small oil tank if desired.

You can buy any part of this outfit at the following prices:



V-shaped radiator, brass	$25.00	Wood brackets for gas tank	$ 1.50
Taper hood, regular length, with handles	8.50	Round straps for gas tank	1.50
Cowl, rolled edge	5.00	Oil tank, 7½x11x27, or tool box	3.00
Wood dash to fit	3.00	Brackets for oil tank	1.25
Body with wood frame, metal covered	14.00	Round straps for oil tank	1.00
Oval gas tank, 10x16x30	4.75	Long starting crank	1.00
		Upholstered seats, leather	25.00
		Total	$96.50
Nickel Plating radiator, extra			$2.00

Why the TRINITY BELL is to be the *ultimate* type of Warning Signal

A BELL COMMANDS ATTENTION AS NO OTHER SIGNAL CAN

Bred in the nature of every pedestrian and driver, is the recognition of the two universal danger signals—the bell and the red lantern. Years before motor cars were known, these two signals were standardized—and accepted.

Street cars, fire engines, patrol wagons, ambulances, locomotives, street railway service wagons—vehicles that give the alternative, "move or get injured," are without exception equipped with bells.

Made in 3 models: Model A, for smaller cars, complete, $6. Model B, for medium cars, complete, $10. Model C, for limousines, heavy touring cars and trucks, complete, $12. All prices include entire equipment for installation. Special model for motor boats, $12.

The TRINITY answers all requirements of law, and is absolutely guaranteed. Dealers and Owners: We absolutely guarantee that the Trinity bell is not an infringement on any other similar device.

Dealers and Jobbers—The TRINITY BELL is a big seller at a good profit. Write for particulars now.

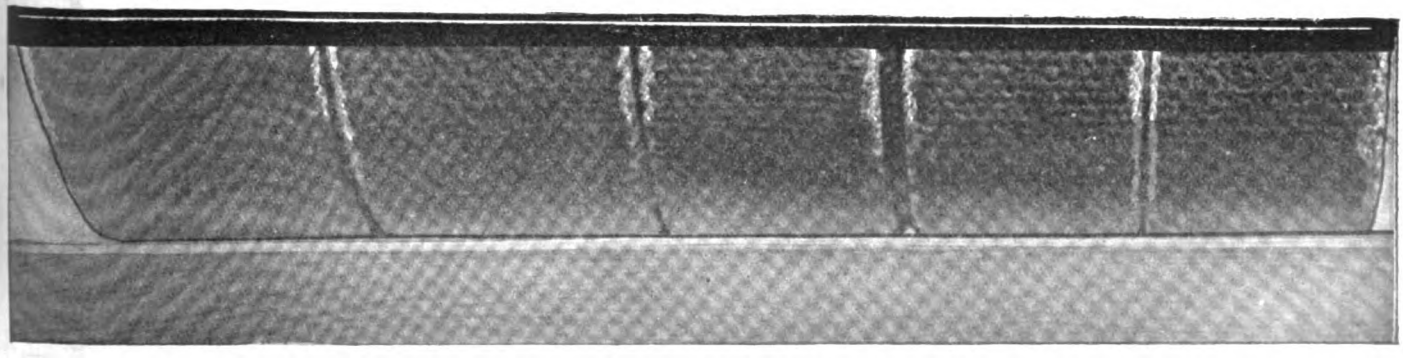
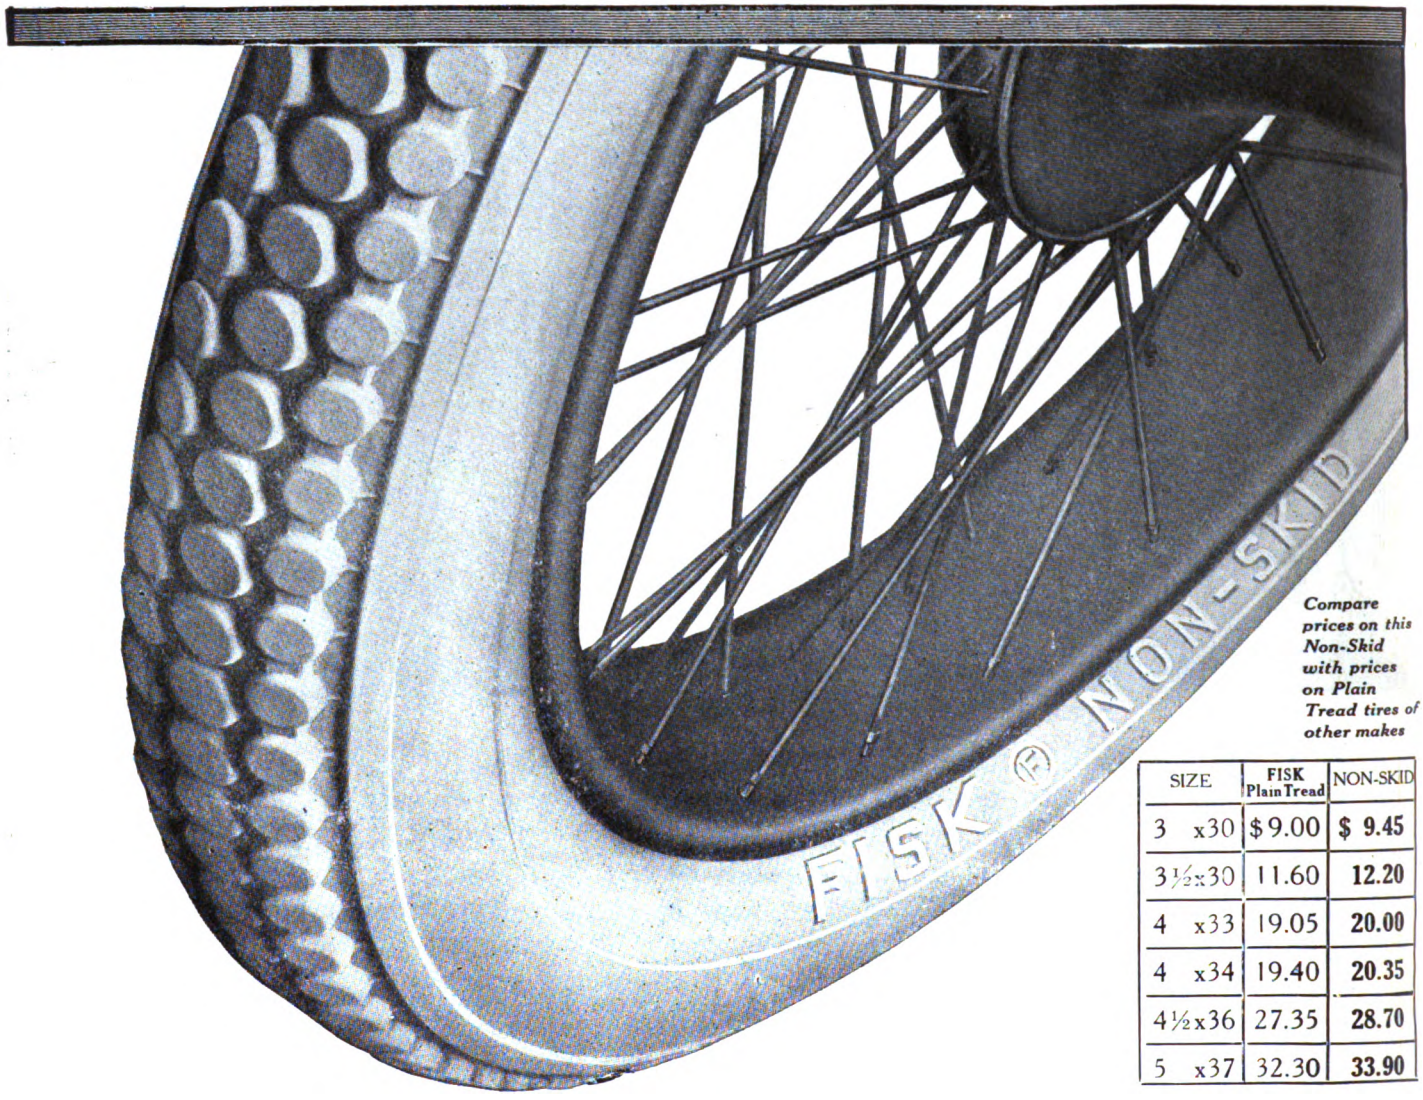
MORE dissatisfaction results from doing business on a consignment basis than in any other way—disappointing to the manufacturer—disgusting to the dealer and disquieting to the user if he should find that either the manufacturer who made the goods or the dealer who sold them did not think enough of the quality of the goods to stand squarely on their feet and do business on a business basis.

RAYBESTOS is not—and never has been handled on consignment—not a foot of it.



The RAYBESTOS system of marketing through distributors—which are in effect direct factory branches—is infinitely more satisfactory, far more economical and in emergency more convenient to all concerned than any consignment arrangement could be.

TRADE MARK Raybestos REG. U.S. PAT. OFF.



RAYBESTOS in all sizes is carried in stock by some one hundred odd reputable concerns located in the various centers throughout the United States and Canada, and each and every one of these distributors carries a stock of RAYBESTOS adequate to meet trade demands. Each and every one of them can and will quote prices equally as favorable as the home office itself. They are prepared at all times to supply the trade with any size, in any quantity, however large or small, and no dealer, garage man or repair man is so far removed from one of these distributors that he cannot send his order by telephone, telegraph or mail and have it filled over night.

Compare prices on this Non-Skid with prices on Plain Tread tires of other makes

SIZE	FISK Plain Tread	NON-SKID
3 x30	$9.00	$ 9.45
3½x30	11.60	12.20
4 x33	19.05	20.00
4 x34	19.40	20.35
4½x36	27.35	28.70
5 x37	32.30	33.90

A Comparison of Fisk Low Prices

THE Fisk Non-Skid, with Fisk Service, at the **Fisk Low Prices,** represents the utmost in tire value. The prices for the Non-Skid are less than charged a few months ago for the Fisk Smooth Tread and **less** than now asked for many smooth tread tires of other standard makes.

Fisk Non-Skid Designed Right

The Fisk Non-Skid is designed **right.** It possesses the mileage, durability and easy riding qualities of the Fisk Plain Tread and in addition a remarkably effective development of traction and non-skid resistance—the kind that prevents serious accidents in an emergency.

FISK
NON-SKID
TIRES
WITH FISK SERVICE

Greatly increased production and distribution make possible these Fisk Low Prices. We hold to the high Quality that has always characterized Fisk Tires and made them the choice of wise and discriminating motorists everywhere.

Fisk Service is Unique

The Service we render tire users is tangible and greatly appreciated. We do all we can to make your investment satisfactory to you, to increase your motoring pleasure to the point where the presence of tires is lost sight of. A thousand trained employees are located in Fisk Branches in all the principal cities to **serve you** with all the helpfulness that the word **serve** implies.

Stop! Throwing Away Your Worn Tires

It's just as unnecessary—just as extravagant—to throw away your tires when they become tread worn or rut worn as it is to throw away your shoes when the first sole gets thin, for you can get 5,000 miles more service out of them by doing what European motorists have done for the past three years. This will result in a saving of from $50 to $200 a year for you.

Don't Let the Junk Man Profit at Your Expense

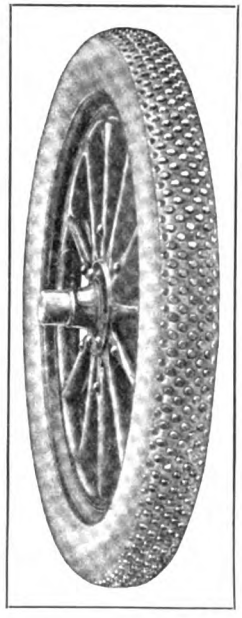
That picture of the junk wagon—with its heap of cast-off tires—illustrates in a striking manner what becomes of the average rubber tire after 3,000 to 5,000 miles of service—uncertain service, with the nerve-racking dread of tire trouble.

This waste in tires is distinctly an American extravagance.

What European Motorists Are Doing

The foremost European engineers have for years been studying the problem of getting more miles for less dollars. With their usual painstaking, scientific thoroughness, they experimented with tire protectors and steel-studded Treads. The result—for over three years European motorists have been "half-soling" their tires with steel-studded Treads just as we "half-sole" our shoes when the original sole gets thin.

These European motorists are getting from 10,000 to 15,000 miles out of a set of ordinary rubber tires, while American motorists are getting from 3,000 to 5,000, and—what is just as important—have almost entirely eliminated the constant dread of punctures, blow-outs and rim cuts.



We Brought Mr. Bullerman to America

When we learned that foreign engineers had perfected a steel-studded Tread that would make a tire run at least 10,000 miles, we set about finding out how they did it.

Then we brought to this country probably the foremost European tire engineer, Mr. August Bullerman, who designed **Durable Treads** along the line of that foreign study and experiment, improved them by new basic patents and made them even superior to the Treads universally used by European motorists. Their success was immediate. In eight months 20,000 American motorists took advantage of this opportunity to cut down their tire expense and eliminate their tire trouble.

Last year the sale of Durable Treads increased 917% in the United States alone. Over 40% of these sales were unsolicited—made through the recommendation of Durable Tread users.

Where is there an automobile acccessory which has received such universal, country-wide endorsement?

How Does This Affect You?

The almost unbelievable waste in tires by the American motorist is not only national—it is vitally personal. It affects you—**your pocket-book.** Just consider what it would **mean to you** to get 10,000, 12,000 or 15,000 miles out of your rubber casings and at the same time drive your car without the constant dread of tire trouble.

In round numbers, it would mean a saving in tire miles sufficient to pay your yearly gas and oil bills by the elimination of punctures, blowouts, rim cuts and skidding—a gratification which cannot be estimated in dollars and cents.

Guaranteed 5,000 Miles Without Puncture

Durable Treads are sold under a **signed guarantee for 5,000 miles of wear without a puncture.** This guarantee is an iron-clad agreement—as good as a government bond—and holds good whether your tires are new or old, tread-worn, rut-worn or rim-cut.

Think of it—to be able to **FORGET** tires! Not once will you have to get out of that car to fix a puncture, and this **tire vacation** is guaranteed to you.

No More Skidding

Durable Treads are as sure-footed as a burro, and they're supremely convenient. Look at them—they're simply bound to be safe. The sharp-edged steel rivets make skidding almost impossible.

In London and in Berlin, as well as many other of the larger cities of Europe, ordinances compel the use of steel-studded Treads for public safety. Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains, and, what is more important—**you receive perfect non-skid service while your tires are protected instead of injured.**

Ask Yourself This Question

Do you intend to continue allowing the junk man to profit at your expense, by carrying away in tire miles enough to pay your yearly gas and oil bills, or will you turn to your advantage the experience of European motorists?

It is the same question of economy you decide when you "half-sole" your shoes instead of throwing them away when the first sole gets thin. Rubber tires cost several times as much as shoes and are certainly worthy of the same economy.

Special Discount Offered

To motorists in territories where Durable Treads have not yet been introduced we offer a special introductory discount equal to the full dealer's profit.

Will you let us give a demonstration at our own expense and risk?

Will you let us make you an offer so fair and square that you do not stand to lose one red cent, either before or after you buy? The time for action is NOW, before the tires on your car run another week in a "barefooted" condition—before you get your next puncture or blow-out.

Cut out the coupon below. If you haven't a pen or pencil handy you can fill it out afterward, but cut it out now before you turn the page and forget. It will be the means of adding at least 5,000 miles to the life of the tires on your car.

THE BOSCH MAGNETO

has proved its claim—the best ignition system. A broad claim perhaps, but built upon deeds and facts that prove their case beyond a doubt.

For the future, the Bosch Magneto promises to hold its position of supremacy, for every 1915 race of prominence run, has been a Bosch victory and the lengthy Roll of Honor of 1914 and those of previous years promise to be exceeded.

There are no greater nor could there be more impressive proofs of Bosch superiority, than the list of victories given here—not only because they prove Bosch Magneto Ignition more speedy, not only because they prove Bosch Magneto Ignition more capable for easy starts and quick "getaways," for strength and intensity of spark, but because they prove Bosch absolutely reliable. A broad claim, but the facts are there to prove it, for no test could be more severe than the long grilling grind at the terrific, high speeds evidenced in contests as prominent as these.

When Bosch Magneto Ignition is selected, the price paid in dollars and cents may mean a trifle more to the car maker, but the priceless requirement absolute reliability at all times is there and with it go efficiency, speed, comfort and confidence.

Why The Porcelain Doesn't Break

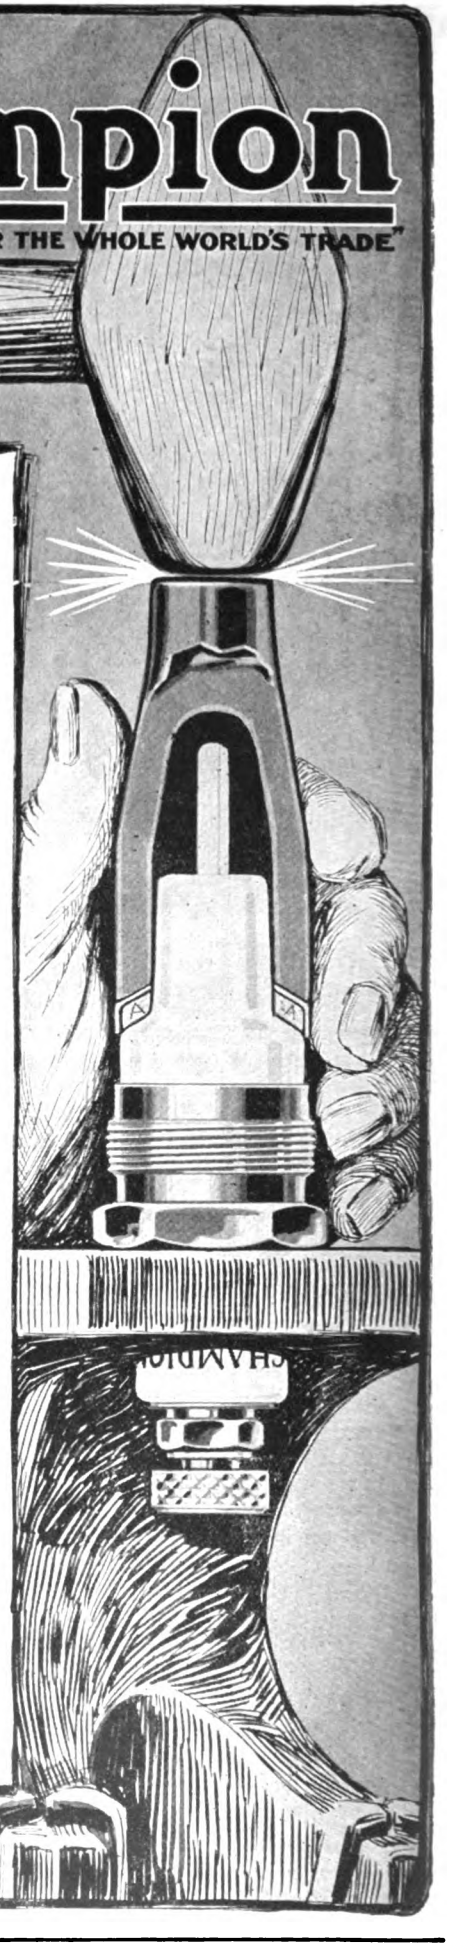
See that **asbestos-cushioned** copper bushing (A in illustration)?

That's where the porcelain insulators in Champion Spark Plugs take the hammerlike blows of the explosions in the cylinders.

We **cushion** the blow by **packing** the little copper bushing with **asbestos.**

That saves the porcelain—also the compression.

This distinctive Champion feature saves Motor Car Owners many a dollar and much annoyance.



This is just one of the reasons why 75% of all American Made Motor Cars are equipped when new with Champion Spark Plugs.

This is just one of the reasons why Dealers so unanimously recommend Champions to Driver-Owners.

Their loyalty to Quality which has led them to recommend Champions so consistently, has entitled Dealers to a share in our profits.

Any Dealer whose strong-box does not contain our 1915 Profit Sharing Agreement should ask his Jobber's Salesman or write to us about it at once.

$48.00 Will Earn $100.00

in three months if invested in a

WEAVER Garage Press

HUNDREDS of these Presses in Garage service have more than paid for themselves in thirty days—so why should YOU continue to throw money away by depriving yourself of this money-making equipment?

Every time you use a sledge to straighten an axle or shaft,—to force a gear or ball race or hub, you lose money in labor and time, to say nothing of the parts which you injure and are compelled to replace.

LEVERAGE 1500 to 1

The lever construction on this Press provides a leverage of over 1500 to 1, so that one man can develop a pressure of 20-tons with very little effort.

DESIGNED FOR GARAGE WORK

Crank shafts and similar bulky pieces can be very readily handled with this Press by reason of the divided bolster, as shown herewith. The bolster may also be adjusted to the extreme bottom of the frame, giving a capacity of 48 inches between it and the screw.

The frame of the Press is 32 inches in width, allowing it to receive the largest automobile wheels for pressing out hubs, bearings, etc.

VISE-BLOCK ATTACHMENT

A "vise-block" is provided which operates between the screw and bolster for the purpose of holding axles, shafts, etc., against a twisting strain.

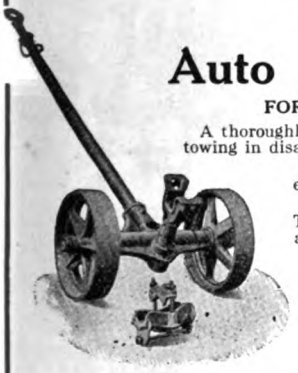
CONSTRUCTION

The frame is one piece of heavy channel steel; the hand wheel is 15 inches in diameter and the weight of the wheel and screw is carried upon ball bearings. The hand lever has a leverage of over 1500 to 1. The thrust of the screws is directed against heavy Bronze Thrust Bearings. The screw is 2 inches in diameter with 3-pitch Acme thread, and has a range of movement of 12 inches. **The Screw Does Not Revolve.**

The bolster which carries the plate can be set at any desired height with extreme adjustment of 48 inches. The width between frame uprights is 32 inches, height 74 inches, floor space 36x36 inches, weight 425 pounds.

Net Price, Complete with Equipment $48.00

WEAVER Auto Ambulance

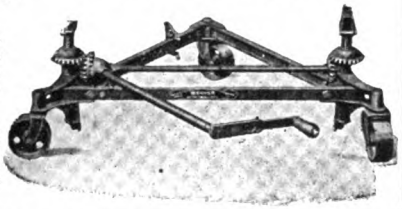


FOR CRIPPLED CARS

A thoroughly substantial and practical device for towing in disabled cars.

Strong, compact, comparatively light, enables one man to do the work of three.

Roller Bearing Cast Steel Wheels; Telescoping steel tongue; 1¼ inch steel axle; full range of adjustment.



LIST PRICE, $30.00

WEAVER Auto Twin-Jacks

The one piece of equipment which enables one man to manipulate a car upon the floor in any desired manner.

Ball and roller bearing casters and lifting mechanism will handle extremely heavy loads with ease.

New York Uni-Coil Ignition System for Ford Cars

PRICE $15.00

It gives all the advantages of the best high tension magneto service. The spark is delivered in perfect time to each of the four cylinders. No failure is possible at any speed. Greater power, speed and flexibility is attained by its use.

Operated by the Ford Flywheel Magneto or Battery

It increases the efficiency and perfects the timing of the Ford Magneto to a degree that puts it in a class with the best big-car magnetos. The **vital factors** in **magneto efficiency** are all embodied in its construction—a magneto contact breaker, with but one pair of adjustable contacts—an advanced type of high tension distributor that uses but one of the standard Ford coil units.

The New York Uni-Coil gives the Ford the ignition efficiency of the high-priced cars. It permits unlimited spark advance and assures perfect accuracy in timing at all speeds. It greatly simplifies the Ford ignition apparatus, eliminating the timer and practically all the present wiring. It is readily installed on the car, all necessary fittings and connections being supplied. This equipment includes an **elevating gear bracket which is permanently oil-tight.**

The complete Uni-Coil Ignition System costs $15.00 at retail. Dealers' margin is right—selling terms on request.

NEW YORK COIL COMPANY

MAKE $250.00 A MONTH

REPAIRING AUTOMOBILE TIRES

Sounds like a lot of money—IT IS—A WHOLE LOT of MONEY to be earning CLEAR every month—yet it's what hundreds of men we have established in the Automobile Tire Repair Business are making. You let down the DRAWBRIDGE for SUCCESS to enter into your career by getting into business for yourself. The business for you is one where the investment is small—the returns quick and for cash—where the margin of profit is large—the demand for your PRODUCT or SERVICE constant and ever on the increase.

A HAYWOOD TIRE REPAIR EQUIPMENT

answers to all of these requirements of Old Dame Fortune—the certainty of success in this business is as sure as anything in this world can be—Each year adds thousands of new Automobile Owners—they need YOU to keep their tires in service.

HERE IS YOUR OPPORTUNITY!

Be first to enter this new, big paying business in your town. Open your pockets. Let the dollars pour in. Act quick. Every auto sold means more tires to mend. Automobile business is growing fast—enormous field for tire repairing. Punctures and blowouts are common. Tires need retreading and vulcanizing. Something going wrong all the time. Thousands forced to buy new tires because they can't get old ones fixed. Think of the old bicycle days—repair shops on every corner—all making money—busy day and night. Autos make same proposition over again—only ten times bigger and better. Users of Haywood Tire Repair Plants are making big money. Johnson, Tex., writes: **"I have made as high as $18 in a day."** Another man who bought a plant September, 1911, writes he has **cleared over $3000.00.** That's going some! Operate a plant as a side line in connection with auto business—garage, or as an independent business. Find neighborhood where there's a bunch of autos—get all the steady business besides transient work. Experience unnecessary. You learn quick. Simply follow directions—practice a few days on a couple of old tires and you'll be ready to coin money. Business comes fast and easy.

THIS MAN IS MAKING MONEY

Repair Tires at Home!

Young men and boys! repair father's tires—get money he pays garage man. Get the neighbor's work. Make money to attend college or to start a garage and repair business. **Auto owners**—repair your own tires—save money—pay for your outfit in short time. We have outfits for home use. Anyhow, investigate. Send today for catalogue. See the wonderful possibilities in this marvelous field. Learn of the enormous money-making opportunities in this fascinating new business.

TUTHILL'S TITANIC
SAFETY-FIRST
Patented Feb 15. 1910
Guaranteed Forever Against Center Breakage

The Spring with NO CENTER BOLT

The Spring with NO CENTER BOLT

KISSELKAR
Every Inch a Car

After exhaustive tests KisselKars are now equipped with

Tuthill Titanic Springs

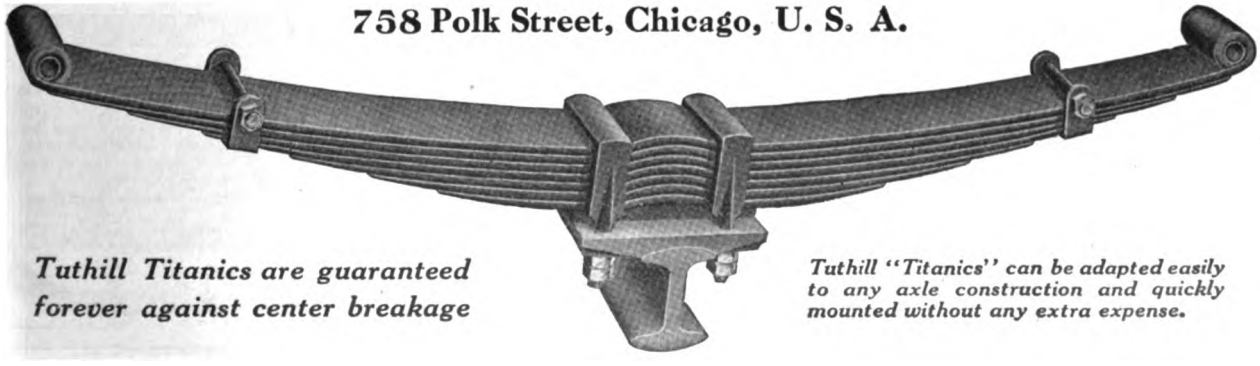
thus adding an increased factor of safety

Now standard equipment

The Kissel Motor Car Company in line with their well known policy of not overlooking any detail of construction that will improve their product have, after a series of the most severe tests, adopted the Tuthill No-Center-Bolt Titanic Spring as standard equipment.

This insures to KisselKar owners a greater factor of safety at the center of their springs—the point which is necessarily the weakest in all springs of the old style center bolt construction.

Fitted to any car



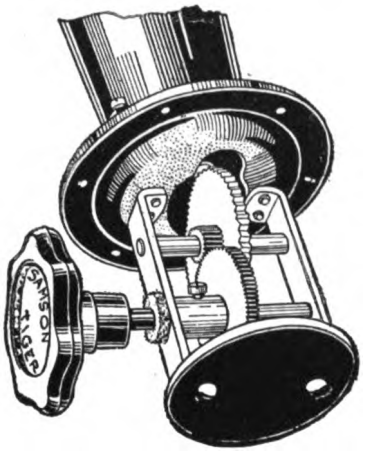
Insist on Tuthill Titanics for *your* new car.

Or if your car is not equipped with Tuthill Titanics and you break a spring, don't take any more chances—insist that your dealer or garage man replace your broken spring with a Tuthill Titanic—it costs no more than the ordinary kind and will last as long as your car.

Service Department: Whether you are an automobile owner or a manufacturer, the knowledge we have gained through thirty-five years in the spring business is at your disposal. If you are having trouble of any kind with your spring suspension write us in regard to same today—we will give you valuable and expert advice.

TUTHILL SPRING COMPANY

758 Polk Street, Chicago, U. S. A.



Tuthill Titanics are guaranteed forever against center breakage

Tuthill "Titanics" can be adapted easily to any axle construction and quickly mounted without any extra expense.

Samson-Tiger

LOOK at this illustration and see for yourself why it is impossible for the Samson-Tiger to stick or refuse to operate. The shaft-drive is the keynote to the satisfaction that this new type of hand-operated horn is giving to its thousands of users. The "push-type" horn, with its lever or plunger, has proven to be too complicated; its many parts have spelled high maintenance cost and trouble for the dealer. Not so with the Samson-Tiger. There is no plunger or lever to stick; there are no springs, dogs, ratchets or other complicated parts to give trouble, and it is equipped with a tone adjuster not found on other horns. *The Samson-Tiger is the only shaft-driven hand horn on the market.* Give it a chance to increase your sales.

Shaft-Driven Hand Horn. List Price $5.00

YOUR CAR, SIR

Represents your personal judgment—whether as its owner, or as the dealer who sells it, or as the maker who builds it.

Its capacity for pleasure-giving **service** depends upon the **service capacity** of the units which, combined, make up the car. The **service quality** of these units, then, concerns you vitally.

The magneto, the lighting generator, the starting motor, for instance—your engine runs right only as your magneto runs right—your lights are dependable only as your generator is dependable—your car starts properly only as your starting motor does its duty.

As owner—or as dealer—or as builder—run over in your mind the names of the magnetos, generators and starting motors that you **know** stand for **maximum service capacity.** Then—

Ask the makers of these accessories what bearings they use. The answer, almost without exception, will be

"NORMA" BALL BEARINGS

Accessory manufacturers who build their reputation into their magnetos, generators and motors—use "NORMA" Bearings.

Car manufacturers seeking to give maximum service capacity to their cars—use "NORMA"-equipped electrical accessories.

Dealers discover that the cars with the greatest demand among discriminating buyers—carry "NORMA"-equipped accessories.

Owners find that the cars that give them the most satisfactory service—have "NORMA"-equipped accessories.

In fact "NORMA"-equipped electrical accessories have come to be one of the features which distinguish the car of maximum service capacity.

As accessory manufacturer, then, why not put **your** apparatus in the "standard" class by using "NORMA" Ball Bearings?

As car builder, why not add to the popularity of **your** car, make its sale easier, by standardizing on "NORMA"-equipped magnetos, generators and motors?

As car dealer, why not insist upon "NORMA"-equipped accessories in the line of cars **you** handle?

As car owner, why not demand "NORMA"-equipped accessories as the electrical equipment of the car **you** buy?

We will send on request a list of electrical automobile accessories using "NORMA" Bearings. You will recognize the names as those of the leaders.

Put a Punch in Your Motor

With—

LEAK-PROOF
PISTON RINGS

MADE BY McQUAY-NORRIS MFG. CO., ST. LOUIS, U. S. A.

THEY secure perfect compression of each fuel charge and the utilization of the whole force of the succeeding power impulse. They also prevent impairment of valve action by carbon caused by surplus lubricating oil getting up past worn or imperfect piston rings into the combustion chamber of the cylinder.

The patented two-piece, angle-to-angle interlocking construction is the exclusive LEAK-PROOF design —absolutely essential to true LEAK-PROOF service. It is the only mechanical principle by which exact fit, equal and enduring tension of a piston ring can be obtained. Look for this feature--identify the LEAK-PROOF Ring – insist on it when you order.

Sold by all up-to-date supply houses, garages and repair shops.

The Staude Glare Stopper attaches to any make of wind shield. The pure amber glass protects the eyes of the driver from all bright and glaring light.

THE STAUDE GLARE STOPPER

The Staude Glare Stopper is the practical solution of the headlight trouble, solved from the right end.

Don't allow your customers to dim their headlights. Every motorist needs all the light he can get. The Staude Glare Stopper protects the eyes of the driver from all bright and glaring lights.

The Staude Glare Stopper fits snug and looks trim.

The Staude is not an experiment. It has been tested out in the Twin Cities for over a year. It has no competition. If you stock it at once it will mean quick turnovers and large profits for you.

The heavily nickeled clamp attaches to any car on the top or side of the wind shield, for either a right or a left hand drive, and is kept perpendicular regardless of the angle of the wind shield. The specially prepared clear amber lens glass, 6¼ inches in diameter, is ground and polished to order.

Send us $2.50, the retail price for one. If you are not convinced, after seeing and using it, that you can't get along without a Staude Glare Stopper, return it and we will refund your money. If you like it and order more, we will quote you dealer and jobber prices in quantities and give a refund on the one you already have.

The Staude is the sensation of the times.

What's the Answer to the Blow-out Question?

But they can't save you from the expense and risk of blow-outs if they are not on your car

A BLOW-OUT is more than a nerve racking noise—more than the ruination of a tire—more than losing control of the car—it is a positive danger! It comes from the inside, from a bruised, weakened, brittle and lifeless fabric—the backbone of the tire.

The Miller Method prevents blow-outs by eliminating their cause—by retaining the natural vegetable wax and oil in the cotton fabric. By not deadening the life of the fabric during manufacture. Oil carbonizes at 240 degrees. The old method of tire building requires 287 degrees to vulcanize a tire. The Miller exclusive process vulcanizes perfectly at a low degree of heat. It makes a rugged unit of both fabric and rubber—without destroying the natural wax and oil of the fabric or burning the native toughness out of the rubber.

The result is a tire that gives you practical immunity from stone-bruises, and the blow-outs that follow.

Perhaps it does not interest you what is put into a tire. It's what you get out that counts. But *you can only* get out of a tire what has been built into it.

In every Miller Tire there is

—additional care used in compounding rubber:
—an extra price paid to procure exactly the right cotton fabric and rubber:
—added time spent to secure the very best workmanship:
—the "Miller Method" of vulcanizing that keeps the life in the rubber and retains the natural wax and oil in the cotton:
—a greater number of inspections to make sure that each part of every tire is perfect:

Together, these items make a big sum total that insures the purchaser of a Miller tire additional mileage, safety and freedom from irksome roadside repairs.

Go to the nearest Miller dealer. When he equips your car with Miller tires—you can put the blow-out question out of your mind.

Miller **Geared-to-the-road** Tires gear your car to the road through mud, sand or slush. **With Miller tires on your car you're in control. Its tread is an integral part of the tire and retains its safety features until the entire tire is worn out.** The greater mileage you get from them, will make your choice of Miller Tires an economy, as well as a permanent safeguard.

MILLER TUBES answer the tube question.

The New York Automatic Head Light Controller For Ford Cars

PRICE, $5.00

PATENT APPLIED FOR

Uses the regular Ford magneto, no batteries, charging devices, or complications. Every Ford owner will be vitally interested to learn that we have perfected a device that is applied by anyone in ten minutes, which will cause the regular electric light equipment on Ford cars (that have been installed by the owner or by the Ford Company) to deliver a powerful penetrating light at all speeds, *including the lowest speed at which a Ford car can be run.*

The Controller is *entirely automatic* in *operation* and at the same time wonderfully simple in construction. In addition to furnishing a strong light at all times, it prevents the burning out of the lamps at excessive engine speed. All the labor necessary is the removing and replacing of a single bolt together with the simple connecting of three wires.

No belts, gears, or moveable connections to the engine are employed.

It is the first and only solution to the electric head light problem on Ford cars. A trial of ten minutes will demonstrate its value. You need one—Why delay? Remit $5.00 now with the understanding that purchase price will be refunded within thirty days if you are not convinced that you have received the largest $5.00 worth in your experience.

Our booklet tells a complete story. Gladly sent upon request.

NEW TRADE APCO MARK FORD SPECIALTIES

THE APCO SPARK PLUG

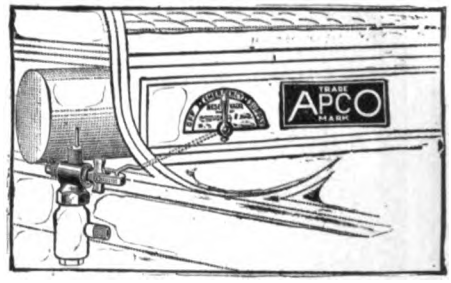
When everything has been said about spark plugs, the fact remains that there is very little difference between any of the high grade plugs except the amount of money spent on exploiting them. The new **Apco** plug is high grade in every particular and while the price is low, we absolutely guarantee it to be as good as any dollar plug on the market and will replace any that do not give the service you have a right to expect. The bushing and body are blued steel. The electrode is very large and is fitted with hexagon nut to hold wire. Points are bent for Ford use and will not accumulate oil. Plug is extra long and removing from engine is a very simple job. The porcelain which is the most important part of any spark plug is the best money can buy and is extra large to insure against breaking. The time when a dollar is the lowest price for a good plug is gone and when you start using **Apco** plugs you will know it.

PRICE 40 Cents

The APCO Detachable FAN BELT

The best fan belt for Ford cars is not expensive but the installation is a troublesome job. The **Apco** waterproofed Oak-Tanned belt has always been the best that money could buy and with the addition of the detachable feature as shown in the illustration it should be the only belt that you could consider when next you need one. To install simply push one end under lower pulley than over upper pulley, and hook fasteners together **without** clinching hooks. This takes but a jiffy and you had better buy one and put it in your tool box.

PRICE 50 Cents

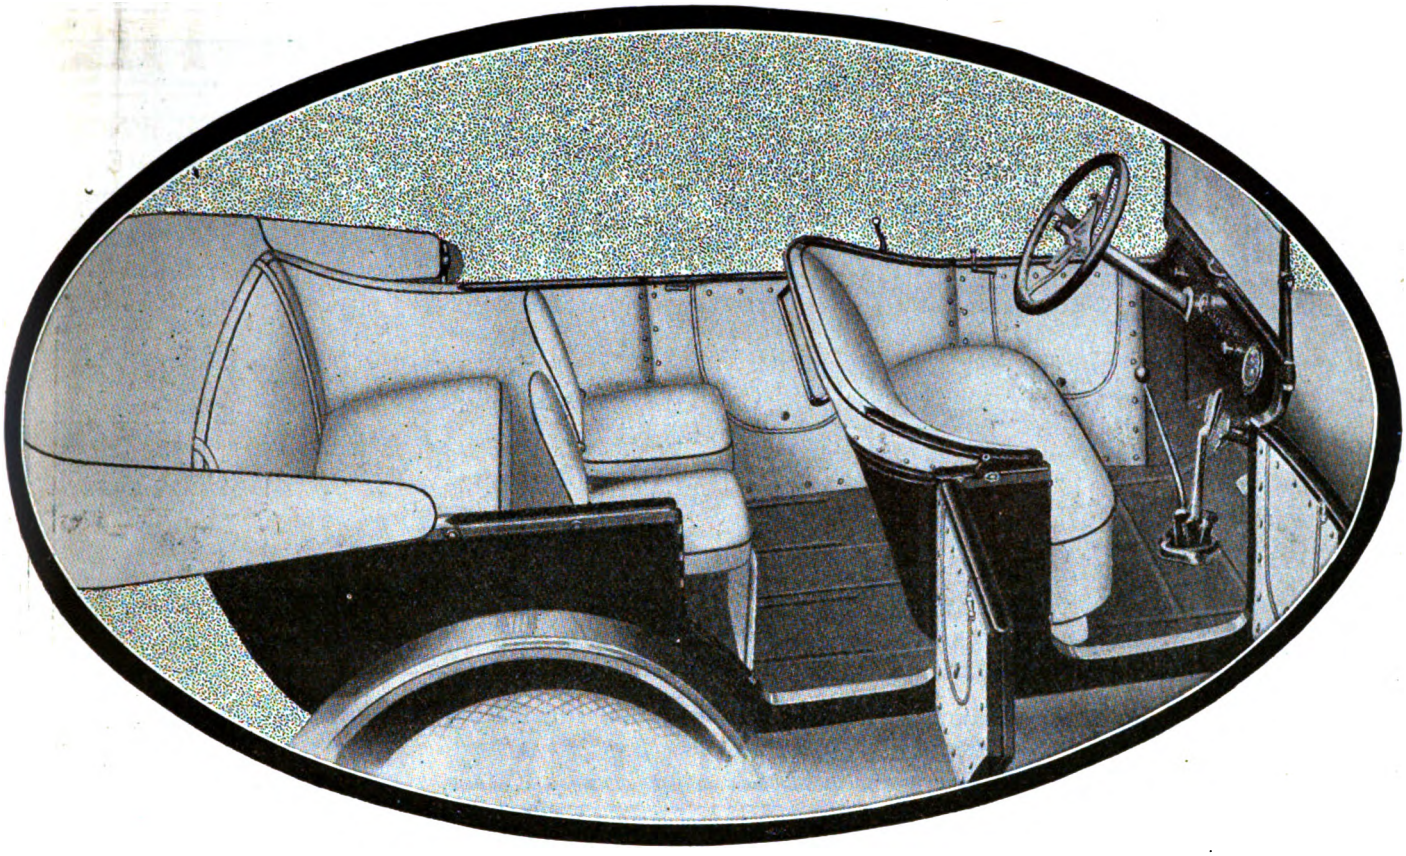


THE APCO HOOD ANTI-RATTLER

This is one of the lowest priced accessories we have ever marketed but it is one of the most necessary and desirable. It consists of a long spring with two special hooks that clamp to the hood where hood rests on hood blocks. The spring passes under the outlet water connection and does not interfere with anything under the hood. In practice the spring is pulling both sides of the hood together, which prevents rattle, and when necessary to raise the hood the spring holds it in position either half-way or all the way up. The price is low and the article is one that you need.

PRICE 10 Cents

THE APCO EMERGENCY GASOLINE VALVE



The Apco Emergency Gasoline Valve for Ford cars is the only one on the market with a universal joint in the shut-off lever and a dial to fasten the heel board which shows position of lever. With this device, your car is equipped with a reserve tank holding a gallon of gasoline, enough for twenty miles running. The most experienced drivers often run out of gasoline on the road and if it happens once it means more to you than the cost of an Apco valve. Equip your car today and forever rid yourself of that feeling of uncertainty of your gasoline supply. It can be put on your car in ten minutes, and being made throughout of brass, it will outlast the car to which it is applied.

PRICE $1.00

AUTO PARTS COMPANY, The Largest Manufacturers of Ford Specialties in the World Providence, R. I.

Give Your Car This Luxurious Look

With every efficient mechanical accessory included as regular equipment on the car, the eyes of the automobile world are turned toward greater luxury.

Luxury—with all the added beauty, comfort and pride of ownership that go with it—is the aim of every motorist.

Campbell Detachable Upholstery gives you this luxury in a way no other single accessory can. It transforms the interior of your car into a drawing-room. It is the last word in refinement.

Campbell Detachable Upholstery goes on over your regular upholstery, and is held in place by special snap fastenings, so that it can be instantly removed for cleaning.

It can be obtained for all standard makes and models of cars in a wide range of fabrics and shades at surprisingly moderate prices. Every set is custom tailored to a permanent glove-fit. Its durability is greater than that of cheap leather coverings. See that you get it on your new car, or better still, put it on your old car and make it look like new.

Write for this Catalog

Every dealer, every car owner should get a copy of our new catalog describing and illustrating many other accessories, all sold under the Campbell guarantee. We have an especially attractive proposition for progressive dealers.

Write today for samples and prices

There are Two Kinds of Comfort—Body and Mind—You Get Both With

TRADE K-W MARK REG U.S. PAT OFF

Road Smoothers

QUICKLY APPLIED TO YOUR FORD CAR

They give you the body comfort that comes *only* from motoring "relaxed" in a smooth riding car—regardless of the road's roughness. They give you mind comfort—that freedom from the tiring effort of steering around bumps and ruts so common to the average road. You are relieved of the nerve-racking tension of "picking the road." You get the same comfort as your passengers, plus the pleasure of "no road worry" driving.

K-W Road Smoothers give you this enviable comfort because their design combines three vital factors.

1. A spring to effectively take up the shock.
2. An anti-rebound air chamber to check the rebound.
3. Anti-side motion links to prevent side rocking and swaying.

Each of these features is in itself vital to your comfort and safety. It's only when they are combined in one device that you will get the greatest pleasure from your car. Here's how the K-W Road Smoother fills all these requirements:

The K-W Spring

A helical spring that effectively takes up the shock, made of electric smelted, chrome vanadium steel. The K-W bracket design allows almost ***twice the length of spring action*** or "travel" (in actual service) of any other.

The K-W Air Chamber

The anti-rebound air chamber with its smooth fitting piston acts like a door check, and gently "eases off" the rebound of the spring. This is an exclusive K-W feature. Its design provides a strong, tough, self-lubricating piston, working in a dust-proof air chamber. It requires no attention.

The K-W Side Motion Links

Made of the highest grade heat-treated drop forgings of remarkable toughness. This enables them to withstand the great strain put upon them. They prevent your car from pitching, swaying or skidding while making sharp turns.

K-W Bushings

All bearings are phosphor bronze throughout. That means long life.

But you can find all of these vital factors *only* in K-W Road Smoothers

K-W Road Smoothers always make good because they are built with characteristic K-W Quality throughout.

But after all's been said and done, it's results that count; and the K-W guarantee covers not only workmanship and material, but *results* as well.

$15 SET OF FOUR ONE FOR EACH WHEEL

K-W Road Smoothers are quickly and easily attached. No holes to drill and no tools necessary except a wrench. And the final and biggest advantage you get from K-W Road Smoothers is that they increase the radius of your car's usefulness, and bring you home with that "satisfied feeling" after a day of comfortable motoring.

If your dealer can't supply you, sent prepaid upon receipt of price.

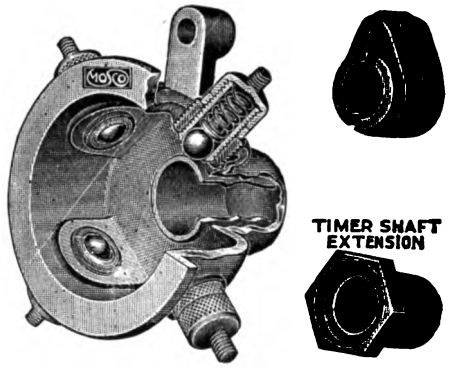
FOGG HORN

for FORD *and* METZ Cars

Still going! Still blowing its clear, mellow signal on thousands of cars throughout the land. Some of the skeptics tell us that the electric horn has supplanted exhaust whistles, but we notice that the old reliable FOGG still continues to sell. The reason? Because it is the horn



LOCATED BETWEEN the ENGINE and the MUFFLER

where it gets the full blast of the gas. Also because it has a cut-out in the body. So that in buying the FOGG you get two devices in one—a signal and a cut-out.

PRICE, WITH CUT-OUT, - $5.00
WITHOUT CUT-OUT, $4.50

BEMUS BALL CONTACT TIMER

Every practical man who knows the Ford car recognizes the fact that this short-stroke, high-speed engine requires a Timer capable of rapid, snappy action in the making of contacts and yet having durability sufficient for thousands of miles of running without loss of efficiency.

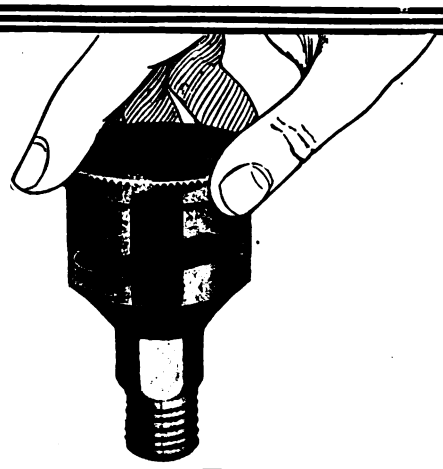
THE BEMUS IS BEST FOR THE FORD
BECAUSE

IT STOPS THAT SKIP. By reason of the method of mounting—on the time shaft—the main cause of skipping is eliminated. You will be surprised at the improvement here.

IT SMOOTHES OUT THE RUNNING to a degree which you would have believed impossible.

IT INCREASES POWER OF HEADLIGHTS. Because of the quicker contact there is a greatly reduced consumption of magneto current, leaving a surplus of current available for headlights. Brighter lights result.

IT GIVES THE MOTOR MORE POWER, MORE SNAP, STEADIER PULLING, AND DOES AWAY WITH THAT JERKY RUNNING ON LOW THROTTLE.



PRICE $2.25

KLICKET
Ratchet Grease Cup
"HEAR IT KLICK"

The Cap Locks On

You can't lose the cap from the "KLICKET" Ratchet Grease Cup. Easily put on and adjusted with one hand. But it can't come off—unless you unscrew it.

Simple, sturdy interior key keeps it safe. A new one free if you lose the cap or any part breaks. One set guaranteed to outlast any car.

No more grit in the bearings. Makes a loud "klick" at every quarter turn. No more guesswork about the amount of grease forced in each day. Adjusted as accurately in dark as in daylight. Threads cannot cross. Made in all sizes—for all cars—in steel, brass and nickel-plated. At your dealer's for 15c and up.

Handsome Free Counter Display

To every new dealer we give this striking two-color display card—19x39 inches in size. It sits on the counter, in the window, anywhere. Card is punched to carry 3 dozen assorted KLICKETS. They sell at sight. Place it on your counter and get sales you are missing now. Make more grease cup money without any more investment.

Write for Sample

Send 25c for sample KLICKET. Just give inside diameter of cap, size of pipe thread required on bottom of cup, or diameter of bearing hole. Return KLICKET if not O. K. Your 25c credited on first stock order.

Get our attractive dealer proposition and prices. Your jobber will gladly supply you with KLICKETS. Write now.

(PATENT APPLIED FOR)

NEW FEATURES OF PISTON RING CONSTRUCTION YOU CANNOT AFFORD TO OVERLOOK

Notice the construction of this ring:

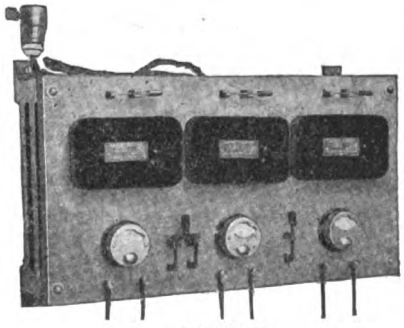
The expander A acting on the bevel on the main ring B forces it outward against the cylinder wall and upward against top of groove, making a *continuous* contact at both these points.

How do *other* piston rings act in worn grooves? At each reversal of motion of the piston the ring moves from one side of the groove to the other, allowing a leakage of pressure and oil around the *entire circumference* of the ring.

Carbon is the result of these small leaks, the oil working *under* the loose rings on the suction stroke.

Ordinary piston rings should fit the piston groove to one-half a thousandth of an inch, or oil will work by, no matter what attempts have been made to make the *joints* tight. How many rings are so fitted? Are yours? How long will they *stay* so?

Pressure Proof Rings are *self-adjusting, always tight.* Can YOU afford to accept a piston ring that does LESS than the Pressure Proof? A proved success. Pressure Proof Piston Rings ask only the opportunity of proving to YOU, in YOUR motor, that a tight piston ring is absolutely essential to POWER, ECONOMY and EFFICIENCY. Satisfaction guaranteed.



If dealer cannot supply you, write direct.

HALLADAY FRICTIONLESS SHOCK ABSORBERS

$9 A Set For Any Car

Heavy Car Type No. 4

At Last—A strictly high grade Shock Absorber at a low **price.** We guarantee there is **none better,** regardless of cost.

We are the largest manufacturers of Shock Absorbers in the world. This new Heavy Car Type No. 4 represents the triumph of years of effort and its low price is made possible only by enormous production.

There is no sacrifice of quality to price. It must measure up to the Halladay Standard of perfection before the name goes on.

Ride behind Halladay Shock Absorbers and **see** how they take up the jolts; then ride **on** them and **feel the wonderful transformation of bump roads into boulevards.** They save not only wear and tear on your car, but also on nerves and backbones, which, by the way, *cannot be replaced.*

Users tell us they save their cost in tires and gasoline alone; **in a single month.** Therefore, it is **real extravagance** to be without them—even if the 100% comfort and pleasure increase is left out of consideration.

STONEBRIDGE SALES COMPANY
10 WALL STREET NEW YORK, N. Y.

A SAVING OF
25% ABSOLUTELY GUARANTEED
In any and all kinds of weather on your GASOLINE in using our
CARBURETTE VAPORIZER
FOR FORD CARS

Start your engine and smell of the exhaust—you will notice a decided odor of gasoline. This means you are not getting the use of all the gasoline which goes into your motor.
This wasted gasoline amounts to fully 33⅓% and is due to the fact that your mixture is not properly vaporized in your carburetor.

Cold Gasoline Will Not Give Off A Vapor

The Carburette Vaporizer is attached to the exhaust pipe with a simple clamp. Here the heat from the exhaus. is utilized to BOIL the GASOLINE. The hot gasoline enters the carburetor and on coming in contact with the air INSTANTLY VAPORIZES.
This is not a new principle but a tried fact. Boiling gasoline is constantly used by the big racers in the middle of summer.
By compelling this absolute vaporization your gasoline consumption will be from 25 to 50% less (our own comparative test shows 50%), not only this but you get

INCREASED POWER REDUCED CARBON
INSTANT ACCELERATION

The Carburette Vaporizer is a positive filter, now a recognized necessity in these days of low grade gasoline. We have provided drain cocks so that sediment and impurities boiled out may be drained off.

PRICE ONLY $2.50
And if not satisfied money refunded

Simple, not complicated, any owner can install in one-half hour. Order from your dealer or through us. Sent C. O. D.

Manufactured by Perkins Appliance Co., Springfield, Mass.

DEALERS!

The New York Master Vibrator For Ford Cars
Price $10.00

Instantly fits the new 1915 models

It was the first successful master vibrator on the market. That was six years ago. It still holds first place because it is the ONE vibrator that does not stick, require frequent adjustment, or give the trouble common to others. A hot powerful spark, easy starting, extreme power, and a smoothness comparable to a six cylinder motor is assured by its use.

A Real Protection Against Theft

OUR NEW YORK KICK SWITCH WITH YALE LOCK. PRICE $2.50

Instantly fits the Ford metal or wood coil boxes.

This is a handsomely constructed **Kick** Switch, but contains a genuine Yale Lock. This switch affords the convenience of a conventional Kick Switch, but possesses the locking feature, which is found in no other type.

Any one can install.

Remit $2.50 for a sample. Money back if not satisfactory.

NEW YORK COIL COMPANY

338-340 Pearl Street **New York**

WESTERN BRANCH: 1461 Michigan Ave., Chicago, Ill.

Micro
Piston Rings

would help you to get much more for less money invested in operating your car.

Money spent in motoring is an investment which you want to keep at a low figure and get the most pleasure from.

Micro Two-Part Pressure-tight Rings substituted for Leaky old style rings will save you money and quickly please you by making a permanent service improvement.

You first notice the better compression through quicker get-away, snappier response to throttle and steadier pulling up hills. The saving of gas and oil, by keeping each on the side of the rings on which it does most good, may not be so noticeable but tests will show this saving to be significant.

The greatest saving and betterment of service, however, results from lessened carbon deposit and consequent coolness of motor, greater regularity of ignition, absence of smoke in the exhaust, and clean valves with less frequent regrinding.

Micro Rings remain as tight when old as when new, and being individually cast from very flexible fine-grained gray iron may be removed any number of times without danger of breakage in refitting.

Micro Piston Rings
The watchdog of a motor's power.

Your judgment in selecting Micro Rings will be more than vindicated on the first installation and you can make the trial at our risk. Business fairness, extensive manufacturing and rigid inspection to micrometer accuracy put backbone into our guarantee.

If your jobber cannot supply Micro Rings don't accept a substitute and be disappointed. Write us direct.

CHICAGO

Repairing Broken Axle

The man in the picture went to the job—repaired the broken axle on the spot in a few minutes, *without dismantling the car,* simply by putting an Imperial Outfit and an oxygen tank in his car and hitching it to the acetylene tank used for lighting.

You are always prepared for emergencies with Imperial Equipment—*on the road or in the shop.* Removes every bit of carbon from cylinders easier, quicker and cheaper than any other method. Don't handicap yourself any longer. *Write us today.*

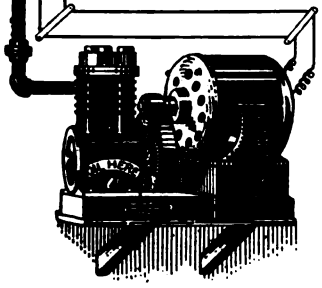
BRUNNER AUTOMATIC AIR SUPPLY



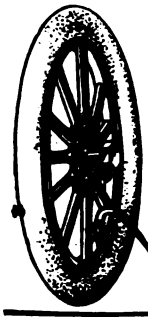
THIS DOES THE TRICK

115 TO 140 LBS. ALL THE TIME

AUTOMATICALLY CONTROLLED

"Always on the Job"

A BRUNNER AUTOMATIC AIR COMPRESSOR OUTFIT WOULD IMPROVE YOUR SERVICE JUST ABOUT 100%



A Brunner Automatic would save you time and operating expense—and **eliminate your air compressor troubles**—because it is a practically constructed, mechanically perfect equipment that has proven by many years of satisfying service to be the "best ever." Any garage man who has one, or any jobber who has ever sold one, will tell you this.

The Brunner Automatic Controller Never Lays Down

because it is a large husky, correctly designed and well constructed instrument built to "stand up" and give you **Brunner Service,** and to you **Brunner Service means** the **best possible service**—if you have ever had your troubles with a cheaply constructed unreliable automatic controller you can appreciate what it would mean to you to have a Brunner Automatic in your garage, it would mean—less worry—less expense, and it would mean more trade and better trade.

It Will Pay You To Investigate The Brunner Line

You might not need a Brunner Air Compressor Outfit right now—but you may need one any minute, and a No. 12 Brunner Catalogue with the name of the Brunner Jobber near your town would be a handy thing to have about the place—because we always carry a large complete stock in our warehouse ready for shipment and a telegram from a Brunner Jobber will start one your way instantly.

PLEASE BEAR IN MIND:—Our plant has been devoted to the **exclusive manufacture** of **Garage Air Compressor Equipment** for many years and there are over 17,000 Brunner Air Compressor Outfits in successful operation—it is not a troublesome side line proposition with us—it's a serious business—and we understand it.

Write for Catalog showing our full line and the name of the Brunner Jobber who covers your territory.

BRUNNER MANUFACTURING COMPANY - - UTICA, N. Y.

For Leaky Cylinders

Superior to All Others

EVER TIGHT

PATENTED AUGUST 6, 1912

A Piston Ring Which Gives Compression in "Out-of-Round" Cylinders as Perfectly as in True Ones

Here is a piston ring that gives 100% efficiency to every type of motor, engine, compressor or pump.

Ideally adapted to use in Automobile and Motorboat engines.

Gives compression when all others fail. No need to rebore worn cylinders—simply install EVER-TIGHT piston rings and the motor is good as new.

EVER-TIGHT piston rings are made up of three individual, interlocking rings, grooved together to give flexibility and reduce friction. This three-part construction is clearly seen in illustrations above. This is the only three-piece piston ring on the market.

If dealers do not carry EVER-TIGHT piston rings, Auto repair men should write us.

Jobbers and dealers wanted everywhere. *Write for particulars.*

THE EVER-TIGHT PISTON RING CO.

1428 CHESTNUT STREET ST. LOUIS, MO.

Stop the Blinding Headlight Glare!

Chaney Automobile HEADLIGHT DIMMER

It enables the driver to graduate the intensity of the light. It can be changed from high to low as you would turn down an oil lamp. Operated by moving the dimmer handle, it gives complete control of the headlights from the seat. In city driving the light is kept low with small current consumption—in the country where full power is needed a touch of the handle brings back the full searchlight efficiency.

DEALERS: Write us for prices and territory.

MOTOR STARTERS.

Various Electrical Systems Employed—Separate Units and Motor Generators.

BY C. P. SHATTUCK, M. E.

The most interesting part of the electrical equipment of the automobile is the motor starter. It converts electricity into mechanical motion of sufficient energy to rotate the crankshaft of the engine at a speed of 150 revolutions a minute, or three times as fast as the average strong person can spin the engine with a hand crank. The motor starter is also interesting because of the fact that although productive of less than one horsepower (generally one-quarter or three-quarter) it will crank a 4½x 5½ six-cylinder motor at from 120 to 140 revolutions a minute, and with an 80 ampere-hour capacity storage battery as a source of current supply.

Considerable improvement has taken place in the motor starter since it was substituted for the hand crank. The units are made considerably lighter, are more compact and accessible, and are highly efficient. The most notable advance made by the manufacturer is the reduction of the amount of current required for starting. When it is considered that the efficiency of the starter depends largely upon the battery, it will be seen that economy of current is a most important factor.

The starting system, that is classed as the separate unit, is very simple, consisting as it does of a motor, switch, battery and two wires. There is, however, the reduction between the motor and the engine, and the method of the application of the energy to be considered. Because of the fact that

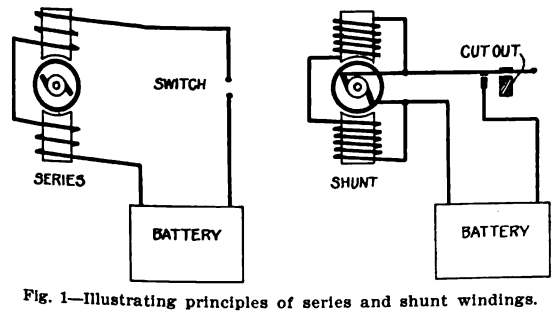

Fig. 1—Illustrating principles of series and shunt windings.

some manufacturers have combined the three functions of the electrical equipment, starting, lighting and ignition, a number of varying arrangements are presented which are not generally understood by the layman, and frequently minor faults of these systems create trouble for the repairmen.

Classifications of Systems.

To simplify the discussion of starters they will be divided into two types, the single or separate, and the two-unit. The single type as previously explained, is utilized solely for cranking. The two-unit consists of a motor and a dynamo, termed a motor-generator; that is, it functions as a motor when current is supplied it, and also generates electricity for maintaining the battery in a properly charged condition and for supplying current to the lamps. This classification is in contrast to that

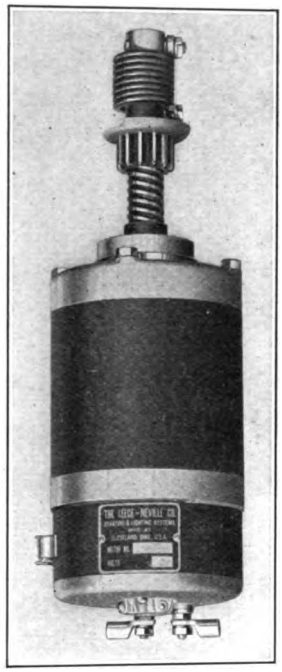

Fig. 2—Jesco Motor-Generator, a motor and generator in the one housing.

usually employed when considering starting, lighting and ignition systems, for the motor-generator even when it includes an ignition distributor is termed a single unit, and the separate motor and generator is classified as a two-unit system. As the various types are illustrated their constructional difference may be easily noted.

A motor and a dynamo are very similar, and their operation will be more easily understood if we apply the fundamental laws of magnetism which are that two unlike poles of a magnet, north and south, attract each other, and similar poles repel. There is an important relation between a wire through which electricity is flowing and a magnetic field. If we take a loop of wire and so suspend it that it will rotate around a supporting member, and connect the two supports with a battery, when a magnet is placed near one side of the loop it will be set in motion. The loop will rotate either toward or away from the magnet, according to the direction of the flow of current. This is the simplest form of the electric motor. If we reverse the conditions, that is, cause the loop to rotate through the field of the

Digitized by Google

magnet by mechanical means, a current will be generated in the wire, and we have the principle of the dynamo or generator.

Function of a Commutator.

In practice, however, the motors do not employ permanent magnets but have coils of wire wound around the frame or magnet core, and the ends of the frame become the poles of an electro-magnet with the introduction of an electric current. Instead of a loop of wire, many loops are employed, and their ends are connected to metal segments comprising the commutator, a copper cylinder which extends around the armature shaft. The segments are insulated from each other by mica, and in contact with the commutator and diametrically opposed are two stationary brushes which are connected to opposite ends of a complete loop of wire on the armature. The function of the brushes is to connect the successive loops to the stationary windings while the armature or rotating part is in motion. A continuous pull is obtained by the connection of successive loops of wire, for as fast as one breaks connection with a segment, another takes its place, automatically shifting the current from one coil to the next in order.

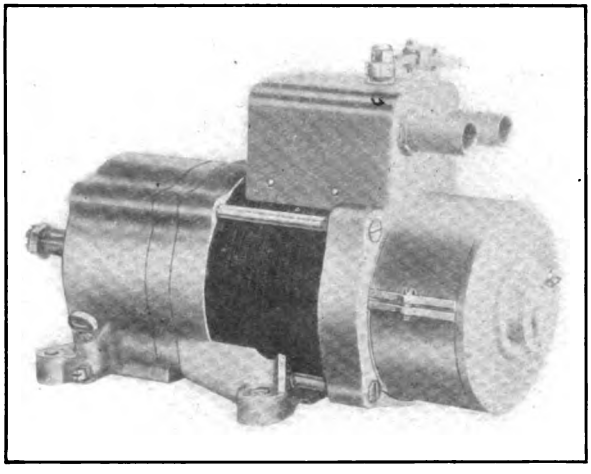

Fig. 3—Leece-Neville series-wound starting motor.

When the electricity is first passed through the armature the unit is known as a series-wound motor. When the current is divided, part of it going through the field windings and the balance through the armature, it is termed a shunt-wound motor. The advantages claimed of a shunt-wound type is that it permits of more positive regulation of the currents passing through it; that is, the amount of electricity flowing either through the armature or field coils may be changed without affecting the other. The series-wound motor is employed for starting as it has the desirable characteristics of high starting torque and diminution of current as the speed increases.

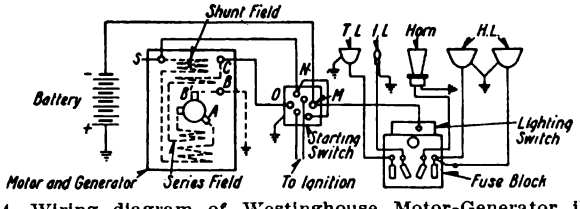

Fig. 4—Wiring diagram of Westinghouse Motor-Generator illustrating wiring of series and shunt-wound fields.

Compound-Wound Machines.

The combining of the two types of windings in a compound-wound unit adapts it for service either as a motor or a generator. A compound winding is obtained by utilizing a shunt-wound unit and placing a series winding around the field magnets. With such a unit both the series and the shunt coils are so wound that both provide a positive pole at one end of the magnet and a negative at the other. When a compound-wound machine is utilized as a motor-generator it is sometimes so arranged that the series winding is utilized when the unit is functioning as a motor, and two separate commutators and brushes are employed for each field winding. The motor-generator does not always consist of two separate windings on the one armature of the same machine, generator and motor windings, but may be two separate instruments within the same frame or housing. These are known as the double deck arrangement. Each have a distinct field and armature, and they may be placed on the same shaft, one behind the other or in tandem fashion. This arrangement is possible as the generator is not functioning when the motor is operating. Generally the double deck units are so arranged that the drive is through the armature shaft of the generator, with a train of gears providing suitable reduction between the motor and the dynamo shaft.

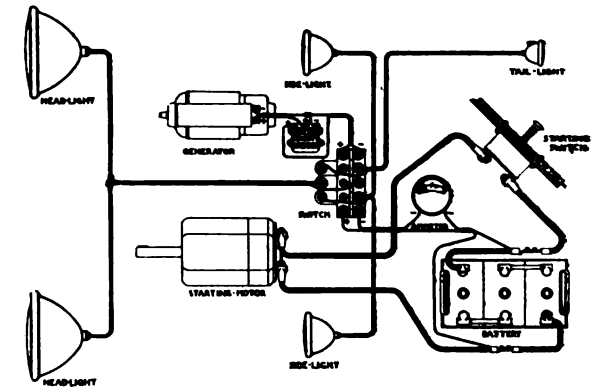

Fig. 5—Two-wire system employed with Auto-Lite motor.

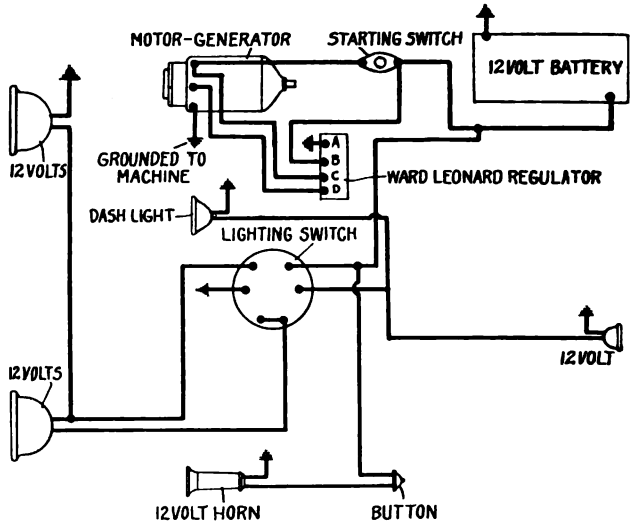

Fig. 6—Illustrating single or ground return wiring of Disco Motor-Generator.

Ratio of Reduction.

As a rule the energy of the motor of the motor-generator is imparted to the crankshaft of the engine by chain, and usually without clutches. The desired reduction is secured through the use of different size sprockets, and the ratio is generally about 3 to 1. Motor-generators are so installed that

Digitized by Google

the engine is cranked through a pinion engaging with teeth cut in the periphery of the flywheel, and the dynamo is driven by the pump shaft. A popular method of taking the drive for the generator is from the camshaft of the engine.

Since the introduction of the motor starter the use of the flywheel of the engine for taking the drive from the motor has been favored by the majority of car manufacturers and this form has gained many adherents during the past year. It eliminates the use of sprockets, chains, over-running clutches, etc., as the desired reduction is provided by the pinion and the teeth of the flywheel. Instances are noted, however, where the separate type of motor is installed at the forward part of the engine, and the drive taken through silent chain or gears to the crankshaft. Exceptions are made

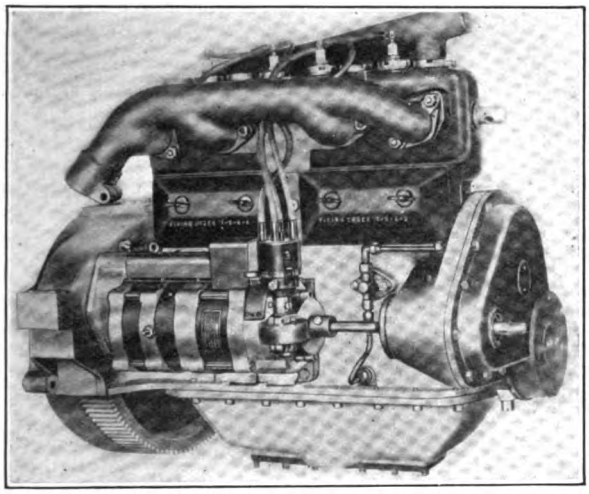

Fig. 7—Jesco Motor-Generator with ignition distributor, also showing flywheel drive of motor and pump shaft drive of dynamo.

to these conventional methods, one maker producing a model that can be installed at right angles to the crankshaft directly in back of the flywheel. The armature shaft of the motor is fitted with a worm which meshes with a worm gear on the clutch shaft, and the drive is through the gearset.

The motor-generator differs from the separate unit in that several types have non-stalling features; that is, at low engine speeds the motor-generator functions as a motor, causing the engine to restart

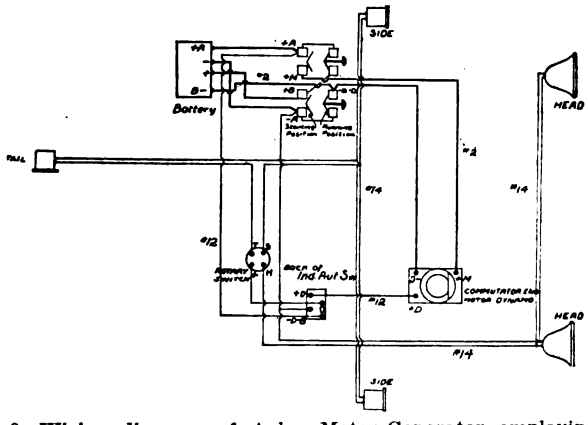

Fig. 8—Wiring diagram of Apico Motor-Generator employing 12 volts for starting and six volts for lighting.

if it stops. One particular model has but one armature, one set of field windings, and is geared to run at a fixed speed, regardless as to whether it is functioning as a motor or a generator. The system consists of the motor-generator, a battery and a switch. The switch is incorporated with the ignition switch, and closing the latter permits current to flow to the motor. Ordinarily the unit operates as a motor for

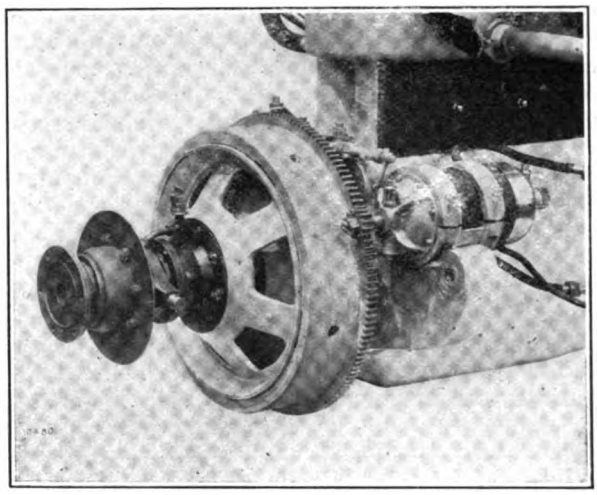

Fig. 9—Illustrating application of Bosch motor, a method very generally employed.

only a few seconds, but as long as the voltage generated by the instrument is below that of the battery the motor will function, aiding in rotating the crankshaft of the engine. Upon the voltage rising, the current generated flows to the battery. The sepa-

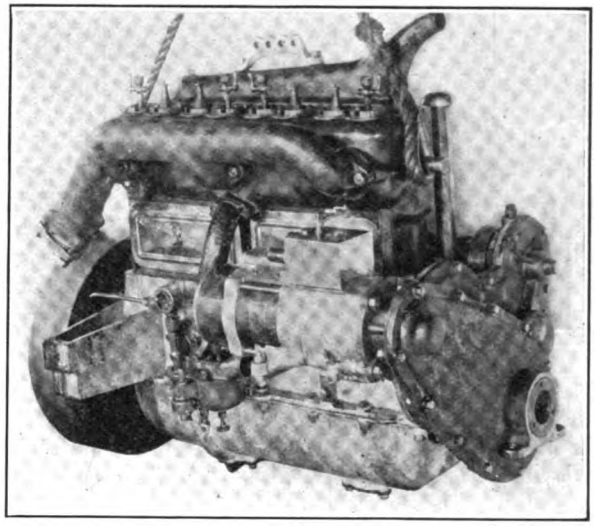

Fig. 10—Jesco Motor-Generator in which drive is taken and energy imparted to crankshaft by a silent chain.

rate unit type operates only as long as the switch is closed and current flows to the motor.

Cranking Speeds Vary.

The cranking speeds vary according to the engine, and a selection of six different types and sizes of multi-cylinder engines show that the engine of smaller cylinder dimensions is cranked at a much higher rate of speed than a large one. For example: A four-cylinder engine having a bore of 2.87 inches and a stroke of four inches is cranked at 210 revolutions a minute, while a six-cylinder engine 3¾ by 5½ is cranked at 104 revolutions a minute. These figures are not exact but will give the reader some idea of the speeds employed.

The current consumed varies also; that is, the draw upon the battery, it ranging from 65 to 150 amperes, according to the motor and the engine.

Digitized by Google

One manufacturer claims that his product will spin a six-cylinder engine having a bore of 3¾ inches and a stroke of 5¼ inches and 60 pounds compression to the square inch, at 100 revolutions a minute with a consumption of 95 amperes. It is estimated that six volts every horsepower developed by a motor draws about 150 amperes from the battery, and that for starting that the rush of current is considerably greater than this. This current draw is bit for a fraction of a second, while overcoming the resistance of starting, and after the compression is overcome the consumption is considerably less.

Wiring Methods Defined.

Both the six and twelve-volt starting systems are used, with the former most generally employed, although the wiring is optional with the manufacturer. One make of motor-generator employs twelve volts for starting and six volts for lighting. Two six-volt cells are utilized and these are connected in

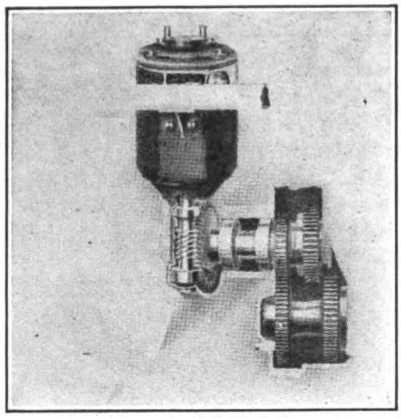

Fig. 11—Unconventional installation of Auto-Lite Motor.

series through the switch. This does not affect the voltage to the lamps as a six-volt current is supplied at all times. Upon the starting switch being released, the two battery cells are connected in parallel and charged as a six-volt unit.

There are three systems of wiring, single, double and three-wire. The single or ground return provides for the positive wire leading from the battery to each of the components of the system, and the other side of each part is connected by a short wire to the metal frame of the chassis. The advantages

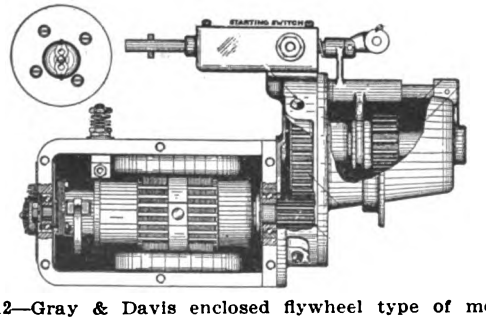

Fig. 12—Gray & Davis enclosed flywheel type of motor.

claimed of the system are: Smaller number of connections, more available space where room is limited, low voltage loss and the elimination of short circuits.

The two-wire system, officially designated as the insulated, consists of two wires, a positive and a negative running from the source of current supply to the components, thus obtaining a complete wire circuit both from and to the battery and members of the system. The most common of the three-wire system makes use of an 18-volt battery of nine cells, these being twelve and six-volts respectively. The

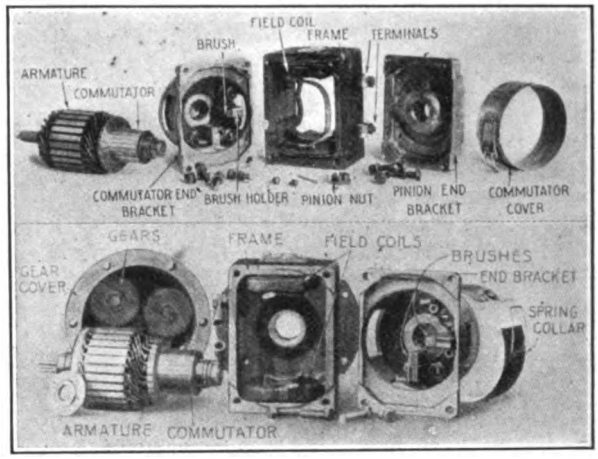

Fig. 13—Components of Westinghouse Motor, showing self-contained reduction gears.

negative poles of the two groups are connected, and this side is wired with the lamps, taking six or twelve volts. When it is desired to utilize a twelve-volt current with any component of the system, one side of the part is connected with the negative wire, termed the neutral, and the other side of the component is wired to the positive side of the twelve-volt section of the battery. Similarly a six-volt current may be obtained.

(To be continued.)

A LESSON IN GEAR CHANGING.

And It Makes a Charming Story of Romantic and Absorbing Interest.

From Wayside Gossip, in Motor, England.—It is quite a romance—my first case. She was a most fascinating little person, with a charming—well, I suppose one should divulge the rendezvous in general before disclosing the precise setting of the scene. It was Brockley Hill—that long deceptive rise from the outskirts of Edgware to Elstree. It is an excellent test hill, and quite a deceptive one. It is usually a case of a low gear climb, and any car which could not climb it under such conditions would not be worthy of the name. However, to our story. I drove up to the difficult spot just near the top in the wake of a two seater Ford, which seemed to go up very well. I then "anchored" my car against the curb and sat me down to see what would happen. It was a glorious morning, and I flattered myself that I was in for some good sport. As it chanced, I was. I had hardly lit a cigarette before I espied my first victim in the distance.

It was a 1911 14-h.p. model, and the sole occupant was the before-mentioned "she." As, perhaps, was only to be expected, she hung on to top speed far too long, until, in fact, she was forced to change. O, that change, and the awful grunting of it! However, the car stood it, and came along very uncomfortably on third. The change had been made much too late, and the little engine did not like it. In fact, it refused to behave itself as it would have done if properly treated, and demanded another change. Reluctantly the fair passenger fell

Digitized by Google

in with the suggestion, and there was a repetition of the clanging of steel. By this time the car with its fair passenger was almost up to my observation post. I was looking at the car and its driver with the minimum of intensity which I could muster—in view of the pleasing appearance attached to the latter. Suddenly she looked up at me—and I don't think she liked me.

I wondered if she had read any of those nasty notes criticising driving exhibitions as observed on certain noted hills. I almost think something of the sort was in her mind, as she suddenly decided to change into low gear, although there was no need so far to do so.

That was the climax. She foozled badly and stopped both car and engine exactly opposite me. As the sound of brakes and so forth died softly away, I heard one little word—something like "dash," only it wasn't "dash." I could not help smiling—until I glanced up and found her looking at me. Then I was quite sure she did not like me. Her eyes were eloquent witnesses of the fact. Luckily I had walked up a little way beyond my car, so that the situation was not yet one of urgency, and the road was reasonably clear. I was now quickly debating in my mind whether her solitude precluded me from offering the assistance which chivalry would instantly have dictated had she any companions with her.

I had just decided to risk it and run out and give the engine a swing, when I found that I was too late. She was out. With one dainty hand she patted the top of the radiator—presumably to see if it was hot "as usual." Apparently she seemed satisfied with the radiator, and then spent a moment or two looking around, and I must admit that she appeared as though everything was quite as it should be, that she was completely mistress of the situation, and that she had really only stopped because she wanted to have a look around. However, another car was now visible on the top of the hill coming down towards us. It was a beautifully lined 20-30 h.p. car, and as fine as one could wish to handle; it had a happy party of people aboard, including some children. The driver, seeing the lady of my story apparently in mechanical distress, slowed down, presumably with the intention of offering assistance. However, seeing me sitting calmly on the bank, quietly puffing away at a cigarette, and the other car just below, he apparently came to the conclusion that assistance was not required.

Anyway, he proceeded on his way. I watched him down the hill and then, as innocently as I could, let my eyes wonder in the direction of Miss Charming, who was endeavoring to start up. As I glanced at her she let go of the starting handle and began to feel the radiator again. That was my chance. Her failure to accomplish something which she had attempted warranted me in intruding (more forcibly) my presence upon her. Trying to look nonchalant, I threw away my cigarette and walked up to her.

"May I be of any assistance?" I queried.

"No, thank you," she replied; "at least, I think it's only the engine that's stopped. It's got rather hard to turn, though."

Well, it had got rather hard to turn; so hard, in fact, that either the clutch had to slip, the gear wheels break, or the brakes allow the car to travel forward, before it could turn to any appreciable extent. In short, the change-speed lever was comfortably ensconced in the low gear position. Fortune was favoring me.

"It is rather stiff," I said; "perhaps it would be better to wait until the engine cools a little."

I keenly felt my degradation in descending to this mean subterfuge, but I really wanted to get an opportunity of giving her a lesson in the art of accurate gear changing. She was so attractive in herself that—well, it seemed a pity that any discord should enter upon the scene, and it certainly did enter when she was gear changing. I suggested that I should back the car to the side of the road, to which she agreed. This gave me the chance I wanted, and I managed to get the gear out under the cover of a carefully-manoeuvred cough.

We now began to get on in a less icy atmosphere. Presently she confided that she was only beginning her motoring career, and that she had bought the car second-hand to learn on, and that she was then going to buy a new car. After a short while we became almost affable, and I began to feel that my original smile at her discomfiture had been forgiven. I elicited the information that she was only out for a practice run, had intended having a little lunch in the country by the roadside somewhere, and then to return home.

I thought we had now become sufficiently reconciled to venture a suggestion as to the art of gear changing. I started by referring to the deceptiveness of the hill and its difficult nature. This proved quite a good line, and, to cut a long story short, it was eventually agreed that I should have the honor of giving her a lesson on the hill in question. Needless to say, several cars had passed up the hill by now, but I had been too pre-occupied to study their performances in detail. When we came to cranking over, the engine was quite nice and easy about it, and started instantly, as though to prove its appreciation of the rest which I had so wickedly obtained for it. I turned the car, and we went down the hill.

Conversation was by now much easier, and by the time we were ready to ascend the hill I felt that I could discourse on motoring matters as though I had been duly apointed to the post of instructor.

"There are two ways," I told her, "of making a good change on a hill, and, by both methods, the change can be made successfully at any speed desired. One must always change in good time in any case. One system is known as the double declutch, and the other as the slipping clutch change. With the clutch on this car you can do either, but as it is quite suitable for the slipping change—which is the easier of the two—we will try that to start with. You see, we are now doing 23 m. p.h. on top, and if we let the car go on it would go much further up the hill before a change was absolutely necessary. However, we're going to change now. You see, the clutch pedal is pressed down gently, thus, until the engine commences to race a little—d'you hear it?—and then we merely move the change-speed lever into third, like that. Easy, isn't it? Now, you see, that was quite a good change, and we have the advantage that the engine is still running fast and therefore giving more power than if it had been allowed gradually to slow down on top gear."

At that moment there was a shriek from a 12-

Digitized by Google

volt Klaxon behind, and a well-known West End garage manager flitted by at about 40 m.p.h. on a sporting Spanish car. Almost as he passed us he "nipped" into second as cleanly as possible, and away he went with the engine roaring at about 3000 r.p.m. with an open exhaust. The lesson was not lost on my fair pupil, and a better example of a good change at high speed could hardly have been presented. By now it was nearly time for us to come into second.

"You see," I said, "we could go much further on third before changing if we wanted to, but if we go into second gear, with the engine running comparatively slowly, it will not be able to accelerate on the stiff part of the hill. If, however, the engine is turning at a good speed on second gear when we get to the stiff bit, it will probably be able to keep up its speed till the top of the hill, instead of slowly laboring its way up. Therefore, we change again sooner than we actually need to. There, you see, quite as good a change as the other and nearly as easy, only one has to pass through the gate fairly quickly."

True to my prophecy, the engine did keep up speed well, and finished the climb in good style on the second gear. My fair passenger was quite pleased, and was now so unbending as to prove graciously grateful. Should she try it? Why, certainly. Might I accompany her again in case—er? Er—yes. And so to the bottom of the hill again, as friend Pepys would say.

I must not vaunt my prowess as a teacher, so I must put it down to her ability as a pupil that she managed the climb this time beautifully. She was charmed with her success. I now fear, however, that we have come to the point where the rest of the story of that day cannot be truly said to appertain to my work as a roadside critic. It was not yet lunch time; but I am bound to confess that I studied no more cars that day. After all, one naturally likes to make sure that one's pupil will perfect what knowledge she has already acquired, and, all said and done, I could easily continue my studies with other cars on the morrow.

THE OXY-ACETYLENE TORCH.

The Proper Flame, Its Importance and How to Get It.

BY M. KEITH DUNHAM, OXY-ACETYLENE ENGINEER.

The garage or repair shop using the oxy-acetylene flame has at its command one of the best money-makers possible. It will, as well, make friends by the score if its principles are understood. But the best apparatus in the world in the hands of a man not understanding it, will drive away trade and shatter forever the faith of customers. There are hundreds of garages with oxy-acetylene apparatus, the users of which do not understand even the first principles of welding. To become proficient in the use of a welding flame is not easy; to master its principles and do ordinary repair work, however, is simply a matter of careful thought and some practice.

Two gases are used, acetylene, rich in carbon and very high in heating value, and oxygen, which is air with the diluting agent, nitrogen, left out. The apparatus may be, and usually is, a cylinder of acetylene, a tank of oxygen, reducing valves for both gases, and a torch which properly mixes the two gases. The construction of a torch which will operate without flashbacks and burn the correct proportions of gases is one of exactness and knowledge.

The point that is most difficult to drive home to the mechanic is that this welding torch may be adjusted to give three different kinds of flames, only one of which is correct. To the ordinary man, heat is heat, but the fact is that there are different char-

Fig. 1.

acters of heat and the effect of the wrong flame on melting iron can be deleterious and result in a weak weld, consequently a break in service and the loss of a customer.

A correctly adjusted welding flame is practically neutral in character—it will melt the metal without any ill effects.

A flame with too much oxygen in it—we call it an oxidizing flame—will burn the metal, take away all its strength and leave the metal in just about the

Fig. 2.

same condition as an old rusted iron piece, for rust is nothing but nature's way of oxidizing.

Too much acetylene puts too much carbon in the weld, hardens it and makes it brittle.

Learning to adjust the welding torch so that a neutral flame is obtained is the first principle of successful welding.

Fig. 1 shows the acetylene lighted and blowing away from the tip slightly. Fig. 2 indicates the appearance of the flame as the oxygen is turned on. Note that a cone is beginning to appear in the center of the flame, white in color, verging towards blue. Continue increasing the oxygen until this cone appears as in Fig. 3, sharp and distinct, but stop right

Fig. 3.

there. Failure to do so means an oxidizing flame as in Fig. 4. To make sure the flame is correct, increase the acetylene pressure slightly; if the flame begins to take on the shape illustrated in Fig. 2, decrease the acetylene pressure until the ragged edges of the cone just disappear.

Here is the basis of all the poor steel welds—why that frame broke, why the shaft you built up and turned down was full of holes, why you burn every steel job you attempt, so that learning to adjust the flame is one of the big factors in successful welding.

It is not sufficient to be satisfied that once adjusted the flame will stay neutral. Heat expands the gases and this expansion need not be the same with both gases, so that after you have started

Digitized by Google

welding, the flame should be tested at intervals by increasing the acetylene, as previously outlined.

Flashbacks are at first puzzling and are always a nuisance, the flame burning back into the mixing chamber with a whistling noise and the tip emitting yellow sparks and soot. They cannot always be prevented in the particular torch you may be using but the modern torch rarely if ever flashes. A flashback may be caused by the orifice in the tip being very uneven, by the flame getting in too close contact with the weld, by excessive heat radiated from a hot casting and by an insufficient pressure. When

Fig. 4.

it occurs, the oxygen cock on the torch should be quickly closed and ordinarily the acetylene then burns out, when the flame may be instantly adjusted again. Sometimes, however, it is necessary to shut off both gases and cool the head of the torch by immersing it in water. If the flashbacking is persistent, force the pressure of each gas to the limit—all the tip will stand, without the flame blowing out. Experienced operators usually stop a flashback by pinching the oxygen hose sufficiently hard to shut off that gas temporarily.

The inexperienced operator should not be alarmed when the torch flashes. Accompanied as it is by considerable noise, it is somewhat startling but there is no danger. The gas (or gases) should be shut off quickly, however, since the continued burning inside will destroy the torch.

Here then are the two chief trouble-makers for the beginner explained. Understanding them does not by any means make you a welder. You are simply started right and by thoroughly grasping the importance of the neutral welding flame the first principle is mastered.

CARBON DEPOSITS.

What Causes Them in Cylinders and How They May Be Removed.

One of the worst of motor defects and inefficiency is carbon formation in piston heads and combustion chambers. Unless this carbon is removed in some way it soon becomes impossible to drive the car except with the ignition fully retarded and with the throttle only partly open, so that the hitherto lively car becomes a dead, unpleasant machine which cannot be driven with any pleasure, and requires a change down from top gear on the smallest incline.

All this is well known, yet it cannot be said that all or even most motor manufacturers have recognized the seriousness of the trouble, as it is a serious matter to have an engine which will not run a thousand miles before it is cleaned out, and there are many engines on the market to-day which will not do much better than this, though a few will run up to five and even ten thousand miles without requiring decarbonization. Of course, these remarks apply to the poppet engine only; so far as the sleeve valve engine is concerned, it is extraordinarily insensitive to internal dirtiness, and runs well in the natural condition of an internal combustion engine. Twenty thousand miles and more is the record of the sleeve engine without requiring decarbonizing, and not an exceptional record either. On the other hand, there are comparatively few poppet engines which will run much beyond two thousand miles without requiring cleaning. It is well worth while to examine into the reason for the exceptions, as if this once be appreciated it should be easy to bring the troublesome engines up to the same standard.

For a very long time the main causes of carbonization were not understood; some engines were much better than others, and no one quite knew why. Then, the dust which is inhaled by the engine, excess of gasoline through unduly rich mixtures, lubricating oils which carbonize readily, and so forth, were all blamed, and, to a certain extent, rightly. Nevertheless, an engine with a carburetor in perfect order, with dust filters and other requirements to keep the inhaled air clean, and with the best possible lubricating oil, may carbonize almost as badly as it would without these safeguards.

The main cause of carbonization is oil getting above the pistons. It is generally agreed that, when the engine is working hard with a fully open throttle, comparatively little oil passes above the pistons, but that when running with the throttle closed or nearly closed, the suction in the cylinders exerts itself more and more upon the contents of the crank

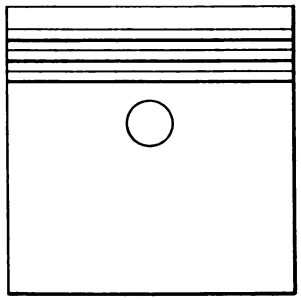

Fig. 1—An ordinary piston with three rings above the gudgeon pin. Sometimes four rings are used, but in any case this type allows oil to pass into the cylinder heads.

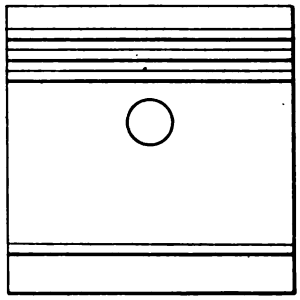

Fig. 2—A piston with a scraper ring near the bottom of the skirt, otherwise identical with that shown in Fig. 1. This passes less oil, but is not much of an improvement.

chamber, as the partial vacuum in the combustion chambers cannot be wholly filled through the restricted throttle opening, and consequently, oil is drawn up past the piston rings. Some of it is burnt in the engine, and expelled through the exhaust pipe in the form of blue smoke, but much of it is only burnt and forms carbon, and in due time the deposit becomes so thick that the engine is rendered more or less inefficient. It is obvious, therefore, that the thing to aim at is a piston which does not permit oil to be sucked past its rings into the cylinder head; the carbonization which then occurs from slightly rich mixtures and from dust and other impurities will not be serious.

All this is a recital of facts which are well known, and while so many engines remain on the market which carbonize rapidly it must be admitted that the mere knowledge of the facts does not appear to have been of great assistance in the majority of cases.

The mission of the piston rings is two-fold, as they have to make a gas and pressure tight, but freely sliding, joint between the piston and the cylinder. Piston rings should not be asked to do more

Digitized by Google

than this. Undoubtedly, ordinary piston rings, while serving well enough as pressure retainers, do not keep the oil from getting above the piston, and to prevent this many makers fit what is known as a scraper ring. This is practically another piston ring below the gudgeon pin, and its mission is not to retain pressure but to act, as its name implies, as a sort of squeegee or scraper to remove the excess of oil from the cylinder walls at or near the base of the piston. Figs. 1 to 6 illustrate various piston designs.

On comparing experiences with owners in many cases these scraper rings appear to be almost useless, and in others quite satisfactory. It is obvious,

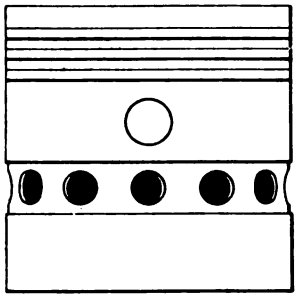

Fig. 3—The piston shown in Fig. 1 lightened by drilling holes in the skirt below the gudgeon pin, but it is little if any better, except for lightness, in the matter of allowing oil to pass.

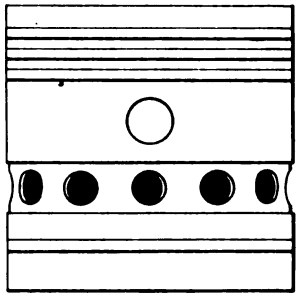

Fig. 4—A great improvement for the scraper ring is relieved of suction by the groove and holes above it, but the oil is forced behind and above the scraper ring.

therefore, that there is some other factor to be considered, and this, we believe, has been recently discovered by one of the Rolls-Royce (England), engineers. The important point which the Rolls-Royce engineer has recognized is that the scraper ring to be effective must not be under the influence of the suction of the engine, so that the pressure immediately above the ring is the same as that in the crank chamber. In other words, if there be no suction on the scraper ring it will scrape the oil away and none will be drawn past it up the piston and beyond the piston rings proper. The word "none" is used loosely here, as, of course, some oil is left, and must be left, on the cylinder walls, otherwise the piston would not be lubricated, but the scraper ring should remove the excess of oil and leave merely a thin film sufficient for piston lubrication.

When we recognize this basic principle we see at once why some scraper rings are satisfactory and some otherwise, as about halfway down the piston there is a groove all around and holes are drilled through the piston walls at this level. This means that well above the scraper ring there are holes in the piston in direct communication with the crank chamber, and that, therefore, the pressure over the lower half of piston and above the scraper groove is the same as the pressure below it, and there is no suction effect. This probably explains why some engines with scraper rings are clean and others dirty, because it has happened that in some cases designers have drilled out the pistons above the scraper ring merely to lighten them, not recognizing that in so doing they were building better than they knew.

The receipt, or at any rate one receipt, for a clean engine may be summarized as follows: Ordinary piston rings above the gudgeon pin; below the rings the piston should have a waist, or reduction in diameter, and holes should be drilled at this point through the piston walls; then at the bottom of the piston there should be a scraper ring, and below the scraper ring plenty of clearance between piston and cylinder to allow the oil to get back to the crank chamber. The same principle can be carried out with the scraper ring a little way up the piston if preferred—and some designers do prefer it for reasons into which we need not enter—but in this case holes must be drilled below the scraper ring so that the oil removed from the walls can pour through them back into the crank chamber and not be forced behind the scraper ring into and above its groove.

So far as we know, this appears to be a simple remedy for the carbon trouble. Of course, we recognize that it is quite possible that other inventors, by some particular form of scraper ring or rings, may be able to overcome the difficulty without removing the suction from the rings. We illustrate, in addition to the more usual designs of pistons, the combinations (Figs. 5 and 6) which appear to keep down the oil satisfactorily, as everyone who has had experience with the later English Rolls-Royce engines knows that they run for very long periods indeed without getting dirty, and this despite the fact that, as they are large engines, they must cover a considerable portion of their mileage with very small throttle openings, when the suction on the crank chamber past the rings is at its greatest.

In the accompanying diagrams it will be noticed that the Rolls-Royce piston (Figs. 5 and 6) has the waist formed with holes through it in line with the gudgeon pin, whereas in Figs. 3 and 4 the waist

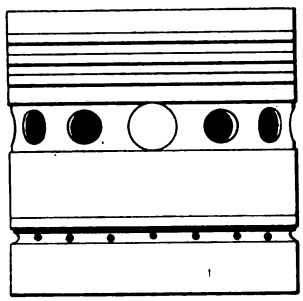

Fig. 5—This design overcomes the defect of the type shown in Fig. 4, as the small holes in the skirt below the scraper ring enable the oil scraped off the cylinder walls to escape to the interior of the piston.

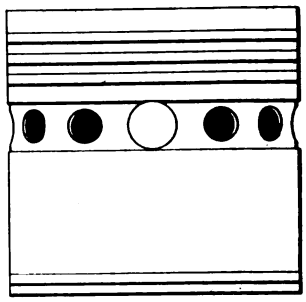

Fig. 6—Either of the designs in Figs. 5 and 6 provides a piston which will not allow oil to pass, because the scraper ring is relieved of suction from above and is untrammelled in its working below.

and the holes are below the gudgeon pin. The latter is the usual method, but possibly the Rolls-Royce arrangement possesses virtues which are not apparent without consideration. For instance, if the holes were larger and lower down they might allow too much oil to get on the cylinder walls above the scraper rings.

The slightest leak between the carburetor and the combustion chamber of the cylinders will tend toward irregular firing, especially when running slowly.

If the paint on a car is not too badly cracked and chipped, it may be much improved by cleaning it perfectly, and then revarnishing it with thin spar varnish.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1613 Exhaust Explosions.

From J. W. Butterfield, Pennsylvania.—I have a Ford car, model T, 1910. I had it overhauled by an experienced man but am having trouble with it. It runs and starts easily, as a motor should that has just been overhauled, but the trouble is that the explosion occurs in the exhaust. It is not a back fire as it does not go through the carburetor. The valves were seated and new springs put on to all but two. It seems to have very good power and the compression is fine. I have tried to overcome the explosions in the exhaust by changing the carburetor and also the vibrator. It has a K. W. vibrator.

Reply.—Explosions occurring in the exhaust indicate missed explosions in one or more cylinders. The unburned mixture of air and gas is pumped into the exhaust, a charge at each alternate upward or outward movement of each piston in the cylinders which are missing explosions. This condition may be due to defective ignition, imperfect carburetion or some other cause, such as a bent exhaust valve stem, weak valve springs, etc. If you will locate the cylinders which are missing explosions, you will probably find that in two or three cylinders the explosions occur regularly. If such is the case we do not see how changing the carburetor, or K. W. vibrator could remedy matters. You may have a defective coil unit, not at all improbable, or the plug porcelain may be cracked, or one or more of a score or two little defects will be found to be the primary cause for the blame all too frequently laid at the door of the carburetor. Muffler explosions most frequently indicate a rather rich mixture.

1614 Life of a Car.

From R. O. M., West Virginia.—I would like to have the editor or some reader, who has had experience, give me some idea as to how much mileage can reasonably be expected of the average thousand dollar car to-day. And if there is any noticeable difference in the life of such a car, if it be used in a practically level country or in the mountains, where the motor must necessarily be pulled much harder.

Reply.—Anywhere from 25,000 to 200,000 miles, depending altogether upon what one means by the "life" of a car, and, of course, as much more upon how the car was used and where it was used. A car will last longer in a level than in a hilly country.

1615 Transmission Trouble.

From L. R. McGaughey, Nebraska.—I have a model 10 Buick automobile. The low speed and reverse is obtained by pushing a pedal forward which contracts a band around the transmission. I have plenty of power with the low speed and can go through anything that the engine can pull through. But when it comes to backing up I have very little power. I put a new lining of Multibestos in both and found that the reverse worked splendid while it was dry and new, but soon become glazed so that I have no power. In fact the old one that I took out was worn but a very little, but I thought that I would put in a new one while I had it out. Is there anything that will cut the glaze and make this band hold on the reverse? Or if that is not the trouble what can be done to rectify the difficulty? The band grips the drum in good shape but it does not hold it nor can one push hard enough on the pedal to make it hold. It has a planetary type transmission.

Reply.—The planetary transmission, standard equipment with all Buick model 10 cars, is subject to wear just like any other gearing which gets severe use. When bushings in the gears become worn the gears operate off their true pitch lines, and much power is lost as a result. There is another prevalent loss of power, if we might call it so, which some users do not seem to realize. This is from a dragging reversing band when operating on low speed ahead, but much more likely from a dragging low speed band when in reverse. Your reverse band should never slip. It is the slipping which eventually causes it to glaze. If it begins to slip and is not properly taken up it will slip worse until eventually it will hardly hold at all. Your statement that the multibestos worked well when new and dry, but soon did not hold should satisfy you that proper attention was not given it when new to prevent initial slipping. We advise a new multibestos lining and that it then be given careful use.

1616 A Starting Trouble.

From R. P. Johnson, North Dakota.—I have a 1912 Overland, 35 horse power Schebler L carburetor, Remy magneto, in good condition, new plugs and new dry cells, but this car will positively not start till I warm the carburetor or prime it. When it is warmed up it starts with the first turn of the crank and runs good. It has always been that way. What can be the reason, do you think? I see lots of cars that start with the first turn of the crank even in cold weather. Why the difference? Would a newer model carburetor help, do you think? The car is rather slow to pick up, too. It has run 5,500 miles. Do you think that the crank boxes are worn enough to be taken up? It is a little noisy. Last fall the car didn't run good at all, and after looking everywhere for the trouble, we found it in the auxiliary air valve. The little burr that holds it together was off, so it couldn't work right.

Reply.—It is not at all unusual that your car will not start until the carburetor is warmed and primed. With the present hard to vaporize gasoline, we don't know of any cars that will start easily in cold weather unless the carburetor is primed and warmed. The model L Schebler carburetor is a good one and your Overland car motor is likewise a good

Digitized by Google

one. We suppose your carburetor is furnished with a heating jacket around the throttle which should be connected with the hot water. Before adjusting the carburetor be sure that your ignition is properly timed and that you have a good hot spark at each plug. See that your valves are properly timed and seated and that all connections between your intake valves and the carburetor are tight. Bear in mind likewise, that the carburetor should be adjusted to the motor under normal running temperature, and not to a cold motor.

1617 **Skips on the Magneto.**

From Dr. E. G. Heaton, New York.—I drive a 1912, four-passenger Mitchell. It gave me absolutely no trouble until late in the fall of 1913, then it began to skip when running on the magneto. If thrown on to the batteries for a minute or two and then back on to the magneto, it might or might not run for a good while before skipping again. All wiring and the switch was gone over carefully without finding the trouble. A Mitchell man told me the trouble was in the coil, but as it was late in the fall I decided to wait until spring before buying a new one. When spring came the trouble seemed gone, and I ran all last summer without annoyance. Now it has appeared again. I ran all right on the batteries but the skipping appears when running on the magneto, especially if the motor has to pull hard. So now I have to use my batteries for heavy work and the magneto for level or down grade. The system is Splitdorf low tension magneto and coil. If the trouble is in the coil why don't I get skipping when running on the batteries?

Reply.—In relation to the missfiring of your car when running on the magneto, the intensity of the current increases with the speed. When running slowly the spark produced in the cylinder will be weak and the charge will be ignited slowly. At high speeds the strength of the current being greater causes the charge to ignite more rapidly. Possibly if you decrease the gap of your spark plugs it might remedy the matter. The gap should not be more than 1/64 of an inch. The current of a magneto, while of greater amperage and heating value, is of less voltage than with the battery system. Of course there is a possibility that your magneto itself may be somewhat weakened, but your letter does not indicate it.

1618 **Misses and Finally Stops.**

From Ford Hawley, Iowa.—I have an Overland, model 60T, 1912. It will not throttle down when idling but will throttle down nicely when pulling. When I crank it up I have to keep the throttle one-fourth open or it will miss and finally stop. When the motor is speeded up or pulling it runs fine. It seems to run a trifle better on the batteries. I took the motor down this spring and cleaned out all carbon and ground the valves. I have a Schebler carburetor, model L, but I do not think it is in the carburetor. I have tried adjusting it. It is equipped with a Remy magneto. The platinum points are in good condition. The car has been run 6,500 miles. I use the light grade cylinder oil. When I am driving it will stop firing on the magneto. I switch on to the battery, run a few seconds on the battery, then switch back and it runs again for quite a distance, then I will probably have to do the same thing over again.

Reply.—Possibly you may not be aware that a magneto does not give quite as good a spark at low speed as at high. However, this may not be the cause of your trouble. Assuming that your carburetion is correct, which you seem to think, there may be an air leak somewhere between the carburetor and cylinders, and this would dilute the mixture more at low speeds than at high. At low speeds and open throttle likewise the compression is greater and a spark is thereby rendered more difficult. Although it may not be the common experience, we have found that as a rule no car throttles down quite as accurately in running idle as when pulling.

1619 **Hudson Car Compression.**

From Charles Ferguson, Massachusetts.—Would it not be possible to get more power and greater economy out of my model 33 Hudson, were I to replace the hollow ended valve cap plugs with solid ones, in order to reduce the clearance and thus increase the compression?

Reply.—Our advice is to let well enough severely alone. You can rest assured that the Hudson engineers use the compression which best suits conditions of reliability, economy and power. Every embryo gas engine designer and inventor seems to have the "high compression bug," but after one experience trying to operate an engine with an abnormally high compression, this malady seldom again appears. There are to-day on the market more cars with too high compression than with too low.

1620 **Ignition Trouble.**

From E. Hallenbeck, New York.—I have a 1911 Cadillac, 30, which has a Delco system or vibrator. This vibrator will start the motor when it is working well, but at present you can crank the motor with the switch in one place, as well as another. This is very inconvenient, because you cannot stop the motor, and more than that it runs the batteries off so soon. The switch has been taken apart and there can be no trouble found in it. I will be very pleased to receive any information along this line.

Reply.—There is undoubtedly something wrong with your wiring, for with the switch lever in the "off" position the battery circuit should be broken, and it should be impossible to start the motor with such setting. The push button normally cuts a vibrator into the circuit. In ordinary running the vibrator is not in the circuit. If you will write to the Dayton Electrical Laboratories Co., Dayton, Ohio, they will send you a diagram of the wiring of this single spark battery ignition system, from which you should be able to trace out the evident short circuit.

1621 **Car Comes Slowly to a Stop.**

From Geo. F. Wardle, South Dakota.—I have a model 31 Rambler car, 2 cylinder, about a 5-inch bore with a model R Schebler carburetor, 1¼ inch. This car pulls good against a strong wind or in mud for about 20 rods, then it begins to slow down, and finally misses. The engine will run all day with-

Digitized by Google

out missing, if I don't pull it for too long a time, then when it starts missing I run it free for half a minute and it is good for another half mile hard pulling. I have taken off all the gasoline pipes and they run a full stream. I have also adjusted the carburetor every way. This trouble started last summer. I had a model L Schebler on at that time. Thinking it was in the carburetor I put on a model R. I use a good heavy grade of oil and have tried all grades of gasoline, some with a real high test, but it make no difference. If you can give me any information, please do so. I have repaired all kinds of automobiles and gas engines for seven years and never had one that would stick me but this. This car runs on batteries, only I use six and eight and master vibrator and it works perfectly.

Reply.—If your statement is accurate, the action of your car is indeed singular, but as a rule when an engine stops slowly and with missfiring it indicates that the batteries are exhausted or the plugs fouled through over lubrication. If the battery is weak you will note a very weak vibrator action and a weak spark. It may be possible, likewise, that there is water in the gasoline. This will sometimes create a condition of the sort you refer to, or the gas tank may be air bound.

1622 Floating Axles.

From M. R. Homer, California.—Kindly explain in your next issue the exact difference between a full floating rear axle, a ¾ floating rear axle, and a semi-floating rear axle, and give some cars that use ¾ floating axles.

Reply.—A full floating axle is one where the

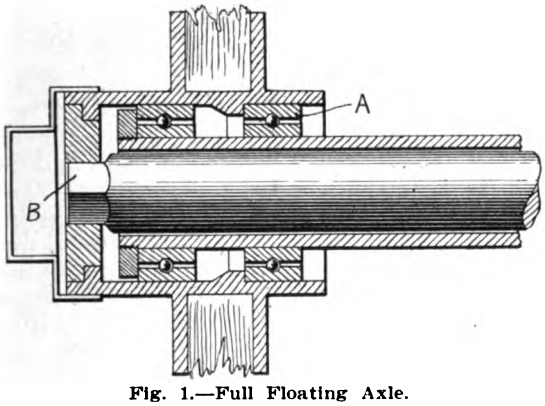

Fig. 1.—Full Floating Axle.

weight is taken from the axle and supported on the housing through which the axle passes. The hubs of the wheel are outside the housing and the bear-

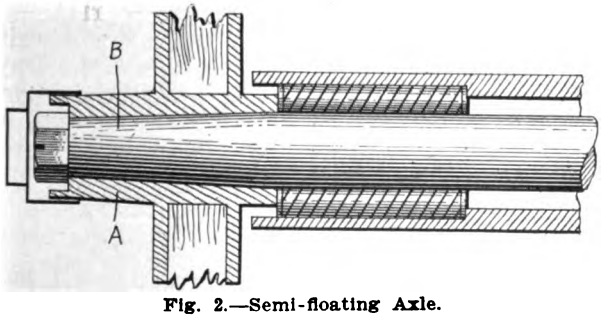

Fig. 2.—Semi-floating Axle.

ings are between the inside of the hubs and the outside of the housing, as shown at A, Fig. 1. The ends of the axle are square, as at B, and over these square ends fit caps that screw or are bolted to the outside of the hub. When the axle revolves, the caps transmits the movement to the wheels. With the semi-floating axle, shown in Fig. 2, the wheel, A, is attached directly to the transverse driving shaft, B, and secured. The driving shaft in this case not only propels the wheel but it supports the weight of the car. The three-quarters floating axle,

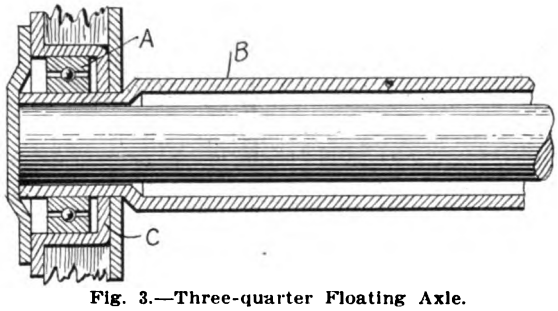

Fig. 3.—Three-quarter Floating Axle.

shown in Fig. 3, is one where the inside ends of the shafts are somewhat flexibly squared into the main differential gears, but the bearings, A, of the outside ends of the axle shafts are upon the outside of the surfaces of the tubular casing, B, and directly in the wheel hub, C, so as to relieve the shafts of the car weight, but the wheels are rigidly fixed upon the shaft ends. As far as we know there are few cars now using the three-quarters floating axle.

1623 A Constant Knock.

From Henry Sechtem, Kansas.—About one year ago I read in your Trouble Department about a Metz car, 22, that had a knock or rather a tapping noise in the engine. I have this same kind of noise, and therefore have been watching your paper for an answer to this, but to date find none. My 1913 model Metz has a knock that sounds like striking or tapping of a steel rod against a solid metal object. I have had the engine thoroughly looked over and tightened up, but the results are the same, the "tick" at every revolution of the engine is still there. This car has run about 20,000 miles, and this noise developed soon after 3,000 miles use. If anyone can solve this for me I should appreciate it very much, as no repairman has as yet been able to locate it.

Reply.—We assume that the knock you refer to is surely in your engine. This indicates loose bearings, if it occurs on level roads and regardless of speed or anything else. It may likewise be due to carbon deposits. Possibly your connecting rod bearings are loose. Of course you are aware that engines will knock if the spark is advanced too far, they will knock if the mixture is too rich and they will knock if the carburetor float is leaking or water-logged.

1624 Misfires at Low Speed.

From R. Strehorn, Colorado.—I have a 1913 model T Ford, which I have driven over 20,000 miles. I have taken the best of care of this car and have never had the engine out of the frames, neither have I replaced a brake band, reverse or low gear band, and have only tightened the high gear twice. So you see I am a careful driver. Of late I have had some trouble in the car missing on a heavy pull on high gear. Running on level ground up to 30 miles per hour the engine doesn't missfire, but in starting after the car has stood for an hour or

Digitized by Google

so, it will miss a few times and then is all right. I have the latest model Holley carburetor, the one without the balls. I have put in eight new valves and they fit the guides perfectly with 1/32 clearance. I rebored my timer and put in a new roller. I have a Connecticut master vibrator. This car is equipped with Kingston coil, which is shorted to suit the master vibrator. Will further state that the car commences to miss only when the throttle is wide open. If I close the throttle two or three notches it stops missing. I have put a gauge on my cylinders and have 45 pounds compression and over on each cylinder. Now what is the cause of this missing? I use Champion spark plugs and heavy Polerine oil. The plugs do not foul up at all.

Reply.—A reason for missfiring at low speed and open throttle is due to the fact that the compression is greater and sparking is thereby rendered more difficult. With an indifferent coil and weakened battery and with some magnetos this is often experienced but not always recognized. There is a bare possibility that your carburetor may be unsuitable for low speeds or may lack proper adjustment, but you ought to be able to decide this point yourself.

1625 **A Missing Cylinder.**

From C. L. Thwing, North Dakota.—I have a model "T" Ford touring car, 1913. It has been run about 4,500 miles. Had it taken down and cleaned late in the winter before the season for use opened. Found it in perfect shape, so the mechanic said. I had a new timer put on recently as the old one showed some wear. Lately it has been missing in the fourth cylinder. I have a Heinze coil and K. W. master vibrator. Thought the trouble might be a defect in the coil, but changed the cells all around and the "miss" is still in the fourth cylinder. The other three are as regular as clock work. Cannot think the trouble is in the new commutator, though I think the miss is a little more pronounced since it was put on. Can you suggest what the trouble is? I think I have read that it is ruinous to a master vibrator to locate a missing spark, by cutting out or short circuiting the different spark plugs by the use of screwdriver, file or other instrument, while the engine is running. Is it true? What is the effect on the master vibrator?

Reply.—Your case is practically the same as described by O. Wallin, Minnesota, appearing in this issue. Our reply to his inquiry suits your case to a "T." Have no fear of possible injury when short-circuiting your spark plugs, except to yourself should you be careless enough to use a screwdriver or file not sufficiently well insulated. When a plug is shortcircuited no extra stress or duty is placed upon the master vibrator.

1626 **Car Lacks Speed.**

From R. E. Melvin, Illinois.—I have a 1915 model T Ford touring car, bought in November, 1914. It has run about 3,700 miles. I seem to have plenty of power, it works fine, and I get 25 miles per gallon of gasoline when I try, but it hasn't much speed. About 35 miles is the limit. I've tried several things, timed it one notch ahead, but on account of kicking so when cranked on batteries, I changed it. The motor seems to get hot quickly on a hot day, when running 15 miles. At 25 miles per hour it will boil and always has done that. Nothing seems to drag or be too tight. I can push it easily and it works well or I couldn't get my 25 miles per gallon. I don't care to go a great deal faster than 35 miles, but want to know that I can should I want to. Other Fords around here run from 45 to 55 miles over the same roads with the same amount of gasoline and everything. Any information you can give will be cheerfully accepted.

Reply.—The heating may be due to the fact that the cooling or lubricating systems are not working properly. After starting the spark should be advanced as far as possible at all times unless the engine labors. Maybe your valves are incorrectly timed or you have a clogged muffler. Your compression may be poor. If the engine gets hot and loses power it may be due to burned gases leaking past the piston rings, which have become worn or broken. Possibly the exhaust valves do not lift enough. Of course when you say your car has plenty of power but lacks speed one would imagine that something may be slipping, but in your case you probably lack both power and speed.

1627 **A Thumping Noise.**

From J. H. Handley, Maryland.—I have a 40 horsepower National touring car, with a 1911 National motor in it, in fine condition. I have had it thoroughly cleaned this spring. However, I find in running the car with spark advanced there is a thumping noise in the motor. When running with the spark retarded there is no thumping noise. The party that cleaned it appears to be at a loss to know exactly what causes the thumping, therefore I write you this letter in the hope of learning the cause.

Reply.—Thumps, such as you are experiencing, are caused either by pre-ignition or lost motion. The fact that your cylinders have been recently cleaned should dispose of pre-ignition as the direct cause. The lost motion may be from worn connecting rod bearings, upper or lower; the upper end of a connecting rod may vibrate from one side to the other; a piston may fit too loosely in its cylinder, or one cylinder may miss explosions. To locate the trouble you should first note in which cylinder the knock occurs. A physician's stethoscope is an excellent means to this end. In all probability you will find it to be in the same cylinder all the time. Of course advancing the spark too far with the motor running at low speed will make any motor knock. Lost motion in the timing control connections will sometimes cause pounding, the timing lever on the magneto not working synchronously with the lever on the steering wheel. When the timing is advanced there is greater pressure exerted against the heads of the pistons, the connecting rods, and crank pins, and a little lost motion might cause practically no pound until the engine is called upon for more work by advancing the spark.

1628 **Fastening Hand Horns.**

From E., Nebraska.—Is it possible to fit a hand horn or a hand Klaxonet, to a Metz car, model 1913, and where could it be placed? I find the bulb horn inadequate in traffic.

Reply.—These signals are usually fitted to the side of the car opposite the entrance, either at the

Digitized by Google

top or by fastening down the inside, the support being from the footboard.

1629 **Gets a Dim Light.**

From R. Blondel, Massachusetts.—Will you kindly answer by letter the following: I have a Ford T car; have a New York Uni-Coil for the timer. I run it on six dry cells and I use the magneto for lighting only. Why is it I can get only a very dim light while running, but get a good bright light when running on neutral. I am using 6 volt, 8 candlepower lamps in series. If I am running 15 miles per hour I get no light, and if I drop into neutral the light flashes out fine, but as soon as I let in the high speed the lights fail. I have it connected up all right, and ground on radiator support.

Reply.—The fact that you are using a New York Uni-Coil ignition system should in no way cause your lights to be poor, as a matter of fact the Uni-Coil system has a shorter contact and therefore will not draw as much current from the Ford magneto as when the regular four vibrating coils are employed. You will understand that the reason your lights burn brighter when you go into neutral is because the engine speeds up immediately upon being released from driving the car. As soon as the high gear is engaged the speed of the motor is greatly reduced. Of course if your magneto has become weakened from use, its current output will become low with a corresponding decrease in light. We would recommend that you have some Ford repairman who is conversant with the matter examine the lights and he can tell you at once whether or not your magneto is below normal.

1630 **Steering Gear Rattle.**

From J. A. Sinclair, New Jersey.—How can I take the rattle out of my steering bar? The car is a 1913 Overland, No. 69 touring. It seems as though the spark rod and throttle rods vibrate in the steering tubing. Can they be wrapped? I don't care to use any filling.

Reply.—You do not state which way the spark and throttle rods vibrate. Sometimes they vibrate what may be termed, up and down, and in others with side play. If you wish to take out the side play, it will be necessary for you to put in new bushings in the top of the steering post. If the trouble is due to end play you should tighten up the nuts on the rods at the top of the rods.

1631 **A Dull Thump.**

From Olof Wallin, Minnesota.—My Ford has run about 5,000 miles and has lately been overhauled. Carbon cleaned out, every bushing that showed least wear has been replaced. Valves that showed least wear on stems replaced with new ones, carbon cleaned out and everything possibly done that a mechanic saw necessary. The car is equipped with the latest automatic advance Atwater-Kent ignition system and with the latest Stromberg carburetor. It has unusually great power and snap but the old and dull "thump" is still heard in the fourth cylinder when the car is running and pulling heavily on the road. If I connect an insulated wire to the fourth cylinder spark plug and short circuit it when the car is running and pulling the "thump" stops. It sounds like hitting with a hammer on the bottom of an empty wooden tub. What is the trouble? We would appreciate very much to find the answer through your paper.

Reply.—Knocks or pounds can only occur from preignition, or as a result of lost motion. The fact that you have had the cylinders cleaned of carbon should dispose of the former possible cause, while to enumerate the conditions under which lost motion could be present to cause the pound we have but to consider the following in the order most usually found: Loose lower connecting rod bearing; loose upper connecting rod bearing; wrist pin hole in the piston not at right angle to the bore of the cylinder. A loose fitting piston sometimes causes a pound, while missing of explosions as the result of defective spark plug or some other part of the ignition system, such as coil or wiring will result in pounding. A loose connection between the crank shaft and transmission would show in the fourth rather than in any other cylinder.

1632 **Throttling Down.**

From B. T. Hinckley & Son, New York.—Am running a 1913 Ford runabout and would like to know through the columns of your paper how to throttle it down (on high) to six or eight miles an hour and still run even. Our crosswalks are bad here and do not like to slip the clutch too often. I turn the carburetor down as far as possible but cannot get below ten miles per hour.

Reply.—We do not believe you could do anything to your engine or car that would permit running it at that speed on high gear, in the manner you seek. With the throttle nearly closed the cylinders are not nearly emptied of the burned gases from the preceding explosions, and there are always more or less leaks of air past the valve stems to impoverish the mixture of air and gas to such an extent as to cause irregular explosions, and missed impulses.

1633 **Quite a Problem.**

From Hiland & Son, Indiana.—We have a Remy magneto on a model 10 Buick, running at crankshaft speed. We can put an armature with a commutator in this and use it to develop probably 8 volt for lighting purposes, direct current. Can we put a suitable armature in this to run this slow and develop about 8 volt, or we could belt it to the flywheel O. K.? If possible to run this slow, how many sections armature should be used, and what size wire? The armature could be 2⅝ by 4½ inches with six magnets 4 by 7.

Reply.—You have a desire to experiment, and if you cannot curb it we advise you to purchase some elementary electrical text books, learn the difference between alternating and direct current magnetos, how a constant voltage may be obtained irrespective of the speed of rotation of the armature and then be sensible and buy a lighting outfit it has probably cost years of effort and thousands of dollars to perfect. Get something that will answer the purpose for yours never will. You have before you a problem of problems. Replying to your query as well as we are able, and probably the engineers of the Remy Electric Co. could not do better, we would advise using all the sections possible and the correct size and amount of wire (which we nor no one else probably knows).

1634 The Schebler Model R.

From S. F. W., Georgia.—Will you kindly explain in next issue of your valuable journal the correct manner of adjusting the model R Schebler carburetor for high speed, low speed, rich and lean mixture? Thank you.

Reply.—The Model "R" Schebler carburetor is a single jet raised needle type of carburetor, automatic in action. The air valve controls the lift of the needle and automatically proportions the amount of gasoline and air at all speeds. It is designed with an adjustment for low speeds; as the speed of the motor increases, the air valve opens, raising the gasoline needle, thus automatically increasing the amount of fuel. The model "R" carburetor has but two adjustments—the low speed needle adjustment, which is made by turning the air cap, and an adjustment on the air valve spring for changing its tension.

The model "R" carburetor has an eccentric which acts on the needle valve, intended to be operated either from the steering column or from the dash,

Sectional View of Model R, Schebler Carburetor.

and insures easy starting, as by raising the needle from the seat an extremely rich mixture is furnished for starting, and for heating up the motor in cold weather. A choker in the air bend is also furnished.

This carburetor is made in four sizes: 1 inch, 1¼ inch, 1½ inch and 1¾ inch. It should be connected to the intake manifold so that it is located sufficiently below bottom of gasoline tank so that it may be filled by gravity under all running conditions. Where pressure feed is used, it is unnecessary to locate carburetor below the gasoline tank; also when pressure is used, it is never advisable to carry over two pounds. Before adjusting the carburetor, make sure that your ignition is properly timed and that you have a good hot spark at each plug; that your valves are properly timed and seated, and that all connections between your intake valves and carburetor are tight, and that there are no air leaks of any kind in these connections. Also the carburetor should be adjusted to the motor under normal running temperature, and not to a cold motor.

When the carburetor is installed see that lever B is attached to steering column control, or dash control, so that when the boss D of the lever B is against the stop C the lever on the steering column control or dash control will register Lean or Air. This is the proper running position for the lever B. To adjust the carburetor turn air valve cap A clock wise or to the right until it stops, then turn to the left or anti-clockwise one complete turn.

To start the engine open throttle about one-eighth or one-quarter way. When motor is started let it run till engine is warmed, then turn air valve cap A to left or anti-clockwise until engine hits perfectly. Advance spark three-quarters way on quadrant, if engine backfires on quick acceleration turn adjusting screw F up (which increases tension on air valve spring until acceleration is satisfactory).

Turning air valve cap A to right or clockwise lifts needle E out of nozzle and enriches mixture; turning to left or anti-clockwise lowers needle into nozzle and makes mixture lean.

When motor is cold or car has been standing move steering column or dash control lever towards Gas or Rich, which lifts needle E out of gasoline nozzle and makes rich mixture for starting. As motor warms up, move control lever gradually back towards Air or Lean to obtain best running conditions until motor has reached normal temperature. When this temperature is reached, control lever should be at Air or Lean.

For best economy and power we recommend that slow speed adjustment be made as lean as possible. Be sure that your gasoline tank and line are clean and contain no particles of dirt, scale or foreign substances, as flooding troubles are invariably caused by dirt or foreign substances preventing needle valve in carburetor from closing.

1635 Carburetion and Ignition.

From S. H. Showalter, West Virginia.—1—Can you give me some information in regard to the 1913 model T Ford car? It seems to run all right when it is standing still, but when I open the throttle three or four notches to put the car in motion, it will choke the motor down. The carburetor is a Holley, 1913 model. What would be the remedy for the carburetor to prevent the choking? 2—How do you test the coil units to tell when they are weaker than they ought to be to run the motor satisfactorily? The car has been run 6,000 miles.

Reply.—1—The early model of Holley carburetor with which your car is equipped has either a parity "loaded" float, or the float is set so high that too large a puddle of gasoline is in the low part of the air passage, the result being on opening the throttle much too rich a mixture enters the cylinders. We believe that the latest model will be found much more suitable for handling the heavy gasoline of to-day. 2—The very best way to test the coil units is to take units from some other Ford car that operates satisfactorily, temporarily replacing your own with them. If the motor misses with yours and does not with the others you could have no surer proof that they need renewing. To test for a broken down or perforated condenser you can open and close each primary circuit. If a spark appears at the ends of the wire as they are quickly separated it would indicate a probable imperfect condenser, for

Digitized by Google

one of the missions of the condenser is to prevent arcing when the circuit is broken.

1636 **His Overland 1912 Car.**

From Geo. Casper, District of Columbia.—1—I have an Overland, 1912. It is model T, No. 60. I have a great deal of trouble pulling hills, unless I put the spark all the way down. If I don't do that it has a rattling, knocking sound. The car came equipped with a Schebler carburetor and a Remy magneto. It is impossible to make it hit on low throttle. After every short trip I have to clean the plugs as the oil oozes through. I have cleaned all carbon and ground all valves but it still has that knock. 2—If there are six passengers in a five-passenger car, and the chains are on, would that cause the front wheels to skid? 3—Or, in riding in second would that cause it to skid in wet weather?

Reply—1—The fact that oil leaks past the piston rings sufficiently to necessitate frequent cleaning of spark plugs in itself indicates the need of new and better fitting pistons and rings and probably re-grinding of the cylinders. You will probably find it necessary to have inlet valve stem bushings renewed and new inlet valves, to prevent leak of air at this point to prevent diluting the mixture of air and vapor to such proportions that it will not ignite regularly with the engine closely throttled. 2—It should not. 3—We do not see how it could.

1637 **Gear Trouble.**

From H. C. Zinn, Illinois.—1—I have run up against a problem I would like to have answered in the Trouble Department. I own a Halladay 30, 1912, made by the Streator Motor Car Co., Streator, Ill., and my problem is the transmission, which is a Warner, 3 forward and reverse. I have the car out and make a stop and when I am ready to start I go into low, make a short run and then try to go to second speed, but I can't get the lever out of low. I can't get back to neutral. The gears are locked fast and I can't get out of low. All I can do is to shut off the power and stop the engine or motor, take the top off the gear case, and take a screwdriver and pry the gears around until the little arm that shifts the gears is in the right place and then everything is O. K. again until the next time, which may be six months and may be six days. This has happened three times in a year, and I would like to know what is the cause, for besides taking time it is a very dirty job and takes the pleasure out of motoring to know you may be up against that job the first time you stop. 2—My car has a Wisconsin motor, Briggs magneto. I have never been able to start on the magneto, but after I get a start on the batteries, which is always easy, it will run fine on the magneto. I never use the batteries except for starting. Why do my batteries run down so soon. I use five dry cells and in the good road season they will only last about two months. I can always tell when they are getting about gone, for the motor will commence to miss on the magneto and will soon get so it won't pull at all on the magneto. I put in fresh batteries and it is O. K. again and will pull like a draft team on the magneto. If you can give me any enlightenment on these questions, I will appreciate it very much.

I will say to G. S. Herbert, Missouri, that he will very likely find his trouble in a leaky gasket and manifold, making the mixture too thin until properly warmed up, the batteries making a hotter spark on slow engine speed than the magneto. As soon as you get plenty of heat and proper speed, the magneto will fire O. K. I had the same trouble and a new gasket was just what it needed, as I had no more trouble.

Reply.—1—This inquiry, it seems to us, would better have been sent to the Warner Gear Co., Muncie, Ind., who would no doubt have been better able to answer it intelligently than we could be expected to. They would also have been able to tell you just what part is defective. We have to say that it looks as if the secondary gear shaft were either sprung or worn, or the bearings needed attention. It seems to us that almost any capable automobile mechanic should be able to divine the cause of the trouble. 2—The magneto is so set that the "peak" or greatest intensity of the spark occurs with early setting. In starting with ignition set late at the breaking of the circuit in the breaker box there is not sufficient strength of the current to ignite the gas in the cylinder. The motor is designed to be started on the battery and run on the magneto. It looks much to us as if you had a short circuit somewhere in your battery wiring, for new batteries should not affect the operation of the magneto. If by any chance your battery is discharging through the magneto wiring you will have more serious trouble. Our advice is for you to send to the Briggs Magneto Co., Elkhart, Ind., for their wiring diagram and look your wiring over very carefully for defects.

Just One Drop of Water.

From R. J. Martin, North Carolina.—I bought a Ford touring car November 27, 1912, and at that time I knew little about an automobile. I have had very little trouble with my machine. I am a farmer and do not drive regularly. I am still using the tires on the front wheels that were on them when I bought it. One of them has never been taken loose from the rim, and as my speedometer has been out of fix a part of the time, I cannot give the exact mileage this car has run, but I will say it has run close to 12,000 miles. I have stopped on the road only once to change tires during this time. I will say for the benefit of J. A. Mandel, South Dakota, that last year I had trouble with my engine. It would start and stop. I asked an experienced repairman about it, and he told me to give it more gas, but that did not do any good. I took the carburetor to pieces and cleaned it and that stopped the trouble. I do not really know what caused the trouble, but I believe it was caused from water in the carburetor. I had read somewhere in the Automobile Dealer and Repairer that one drop of water on the spray nozzle would cause all sorts of irregular running.

Should Be Anything But "Frequent."

From M. L. Mead, New Jersey.—I have owned a Buick, model 19, 1910, car for the last four and a half years, and have never experienced any difficulty in getting my license renewed until recently, and in regard to same would ask if this is of frequent occurrence, and what course you would advise me to pursue?

Early in January of the present year I wrote to the Department of Motor Vehicle Registration, at

Digitized by Google

Trenton, N. J., for license blanks and promptly received the same. The blank for a driving license was filled out and forwarded to the department, together with my check for two dollars and in a few days I received my driver's license card. A few days later I filled out the car application blank, and with this I enclosed a check for seven dollars and a half, and mailed it to the same address, and now have the voucher showing that it was received. For a week or more I watched my mail carefully for the desired word, then other matters absorbed my attention, and as I had letters from the department to show that I had made application, I did not think of the matter again until recently. After a careful investigation I became satisfied that I had not received the card, and therefore immediately wrote the department, calling their attention to the same, and the following is their reply:

"My Dear Sir:—In response to your letter of the 15th, would advise you that we did misunderstand your former letter and thought it was the tags you did not receive. The certificate is always enclosed with the tags and no doubt you have destroyed the same if you did not find it at that time. We cannot at this late date furnish you with a duplicate card free of charge. The cost of the same will be $1.00, and we are enclosing herewith application, if you desire to obtain a duplicate. Yours, etc., Wm. L. Dill."

Free of charge, what do you think of that, after I had remitted $7.50 for it?

Now it isn't the thought of having to pay another dollar that annoys me as much as it is the principle of the thing, and the fact that I have not received that for which I have paid $7.50 and cannot operate my car without.

I should like to hear whether any other readers of your magazine have had this experience and what redress they received if any.

Why He Likes It.

From C. B. Stucky, Kansas.—I sometimes happen to read that someone has quit the subscription of the Automobile Dealer and Repairer just on account of it having so much in it about the Ford cars. Well, for one reason I would not kick on that account, is because there are so many of these Ford cars that it can't be helped. The more the better. I started my Reo car two winters ago, when we had 27 degrees below zero out here in Kansas, without any priming or any boiling hot water or any jacking up of the rear wheels, and throwing it on high speed gears, and turning it on the rear wheels. All I do is turn on the switch, shut off the air on the dash, and with from five to ten turns my motor spins every time. That is a good car.

Wheel Traction.

From "Engineer," Michigan.—I have read with a great deal of interest the article in your February number by James Hobart, M. E., relative to the trials of truck drivers, in starting the cars after being left standing at the curb, or elsewhere, when the ground is covered with packed snow or the streets are otherwise made difficult of passage. The inertia of the front or steering wheels is, as he states where the chief difficulty lies, if not entirely.

The problem has been one interesting to me for years. My means of overcoming this exasperating condition is through a four wheel drive, which I have successfully built in cars for my own purposes. I have found it unnecessary with this arrangement to use either chains or the various expensive non-skid tires. Rubber, as is well known, has extraordinary friction qualities. Where given half a chance, the smooth rubber will give traction on surface smooth as glass. There is something seriously the matter with the design of cars that cannot get enough road adhesion with chains to go through any condition of roads that any reasonable man would expect to travel with horses.

Thus the automobile falls short of giving the necessary all-the-year-round service on schedule which is necessary in industry. So also with the car of the physician that must go at all times and under all road conditions in all localities. The difficulty there lies with even the small runabout or closed coupe type of pleasure car as used by them generally. Complaints are heard in such cases that it is necessary to keep a horse drawn equipment to tide them over bad weather. The "pleasure car" is thus, alas, too rightly named. It has come to be known only as a pleasant weather car. It is in such cases my device as I use it is most efficient, does not detract from appearance of car and has been quite inexpensive to me.

A Narrow Escape

From F. A. Londenberg, Missouri.—Lessons for Drivers is worth the price of the magazine. One in particular saved me from having a serious accident. This was relative to a skidding car. I happened to be caught out in a hard rain, which came up in a hurry. I hit it up, thinking I could make it home. I had a very steep hill ahead of me, and when I had gotten two-thirds way up I learned by the report that I did not have gasoline enough. My wife said, "the back of the car is slipping towards the ditch." I immediately followed your instructions by steering the front wheels in the same direction as the rear wheels were taking." All was well, otherwise I would have landed in the creek. I drive a cross country Rambler, 38 horsepower, and weighs 3,250 pounds. Imagine the consequences if it were allowed to take its course on that dark and dreary night.

For Too Much Oil.

From Charles Fjerestad, Montana.—I have seen so many inquiries in your trouble department, from owners of cars that use too much lubricating oil or else do not have the necessary compression or power. I had the same trouble with an E. M. F. until I saw the advertisement in your paper of the "No-Leak-O" oil packing piston ring. I immediately secured a set and since installing the same I have twice the compression and power and does not use one-third the amount of lubricating oil and about one-third less gasoline. Excessive oil can not get past this piston ring nor can the compressed charge leak past it. I bought these rings from the Automobile Accessories Co., of Baltimore, Md.

Metz Car Power.

From E, Nebraska.—In your April number C. A. Sleeper, of New Hampshire, is right when he says, "The Metz car on hill work can do all that any car, with engine of equal horsepower, can do—and then some." I have driven one for two years, and know.

NOMENCLATURE AND KNOWLEDGE.

A Strong Plea for Elevating the Automobile Business as It Deserves.

From F. L. Angier, Illinois.—We employ a number of men in our shop and we give them all of the various motor magazines, if they desire to read up. There are, however, several features about motor magazines and about the contributors to those magazines which the writer feels should have attention called to. At the present time the motor car industry is not as staple as some of the older industries, but it has long since passed the experimental stage.

When the writer started in the motor car business twelve years ago the repair business consisted of experimenting until you got the job half way correct and a large number of those old types of cars needed considerable experimenting. Today the motor car industry is 90 per cent. perfection and a general accepted branch of service in every city, village and town throughout the United States, but one of the peculiar things of the industry at the present time is the great number of men running repair shops at the present time throughout the United States who have not learned the trade, but simply have tinkered with various makes of cars, until they are able to keep a business based on motor car repairing, afloat.

Perhaps the quickest factor of determining whether these men are really mechanics or just experimenting in the various stages is by reading the letters they write the Automobile Dealer and Repairer. A large number of these men are entirely ignorant of the correct names for a great amount of the simplest parts in use.

There are write-ups appearing in magazines in every issue in which the authors display their ignorance by the terms which they use in mentioning the various tools and component parts of a motor car.

One general term which is being used extensively is the word automobile, and which a great number of men engaged in the industry realize does not give the correct understanding and, therefore, the words motor car, have come into general use. The daguerreotype was a form of photography, still we do not call every photograph a daguerreotype. The greatest number of errors, however, occur in calling bearings, boxes, journals and brasses. Applied to the motor car these words are incorrect.

A very small percentage of the repair men really know that a burr is not a nut, but a washer made in such a way that it will act the same and give the same result as the head on a rivet and is used to put over rivets. The term S wrench is applied indiscriminately to angle wrenches and other various types and ofttimes box wrenches, and dozens of other words which are not applicable to the motor car industry are used every day by men who claim to be mechanics.

A motor car mechanic who thoroughly understands the business has to possess great intelligence, incorporating as the business does a partial knowledge of the blacksmithing trade, machinist, electrician and numerous other occupations. Why, therefore, would it not be advisable to start a course of education in which they can talk intelligently instead of making mistakes which they do?

We know of one man who invariably refers to Whitney keys as half-moon keys and did not know enough to answer a customer over the telephone when he asked for the correct article, that they carried them in stock, and I wish to call your attention to the article appearing in your May issue, which starts on page thirty-eight, written by N. G. Near, of New York, in the statement in his letter in which he took a car out for a test and allowed it to coast with the clutch in and after overhauling the motor found that it coasted further than it did prior to that.

I beg to state that if this man worked for us his discharge would be quick, as the amount of work done on the motor and transmission in taking up the various parts, should have put the motor in such shape that when attempting to coast with the clutch engaged, if the rings were properly fitted and the valves were properly timed and ground, it should not have coasted as far. In fact, if it was a high compression motor with no spark on and the grade was not too great it should have held the car.

We have the only repair shop not connected with the sales business in the state of Illinois, which positively refuses to allow any other make of car to drive in except a Ford and in the last three years our men have done no other work at all except on Ford cars.

We do not wish any other kind of work and devote all of our efforts to give the Ford owners satisfaction and we find that after overhauling a car and taking up the bearings, going over the differential and the transmission and replacing all parts that are worn beyond a certain percentage, the motor when finished is very stiff and very frequently we receive the remark from various customers, "My motor drives and acts like it did when it was new," and we, therefore, take exceptions to the statement that when a car needs overhauling it will coast further with the clutch in than it did prior to that, as it takes from 100 to 200 miles of limbering the car up thoroughly after being overhauled, if a proper job is done.

This letter is written, not in a spirit of criticism, but in a spirit of reminding the various repair men who may read it, that when they write a letter in which their descriptions are not accurate to men who have made a close study of the motor car business, this thought occurs: there must be an awful lot of experimenters working on motor cars.

One of the things which we insist on every one of our men doing who works for us is to take a machinist's catalogue and the various motor magazines and look over the advertising.

If a man will study a machinist's catalogue, issued by any firm which sells machinist's supplies, he will gain more knowledge by a close application to this and other literature than some men will get by working in an ordinary shop for five years. He will know the names of tools and how to use them, parts and supplies by their right names, as well as hints and suggestions valuable in time to come, if recalled and put into use.

Let us make the business one in which, when a man states he is a repair man on motor cars, the public will look at him with new interest and feel that he is a skilled mechanic in his special line, and not just an experimentor who tinkers, that he knows tools, parts and construction and can

Digitized by Google

discuss intelligently such work, without misrepresenting the simplest parts, and if he wishes to discuss shop with a mechanic who combines technical knowledge with experience, he can do so, and not state as a repair man did to us that "the burrs loosened on the pitman and it broke the crank-box and bent the gudgeon pin."

Let us elevate our profession equal to others, mentally, practically and scientifically.

(Note by the editor.—The friendly criticism of Mr. Angier is undoubtedly timely, although there is another side to the matter. His last paragraph is particularly important, however. But one difficulty encountered is that the automobile business or profession is an open field, and anyone can engage in it without an examination for fitness or knowedge. It is thus unlike any of what may be called the "learned" professions. Quite likely the matter will adjust itself sooner or later, and the unfit will be weeded out by the action of a wiser and more discerning public. As to automobile nomenclature, it might be improved, but uniformity of terms will be of slow growth where the field of use is so wide. The same condition exists in other branches of industry, although perhaps not to so great an extent, and likewise in those of hundreds of years of existence. In relation to the coasting of the automobile, the better or worse coasting depends something upon the condition of the car when taken to be overhauled, and what was done in overhauling it. The writer of the article referred to is both practical and honest. He possesses the science to know and the art to do. Yet this in no way militates against the reasoning of Mr. Angier, which is absolutely correct. But automobiles are often overhauled which do not need increased compression, and as stated, how much or how fast a car will coast depends not only upon the amount of compression but upon the steepness of the grade, yet neither fact disproves the statement of Mr. Near. Mr. Angier's communication is not only readable, but in a friendly way, he calls attention to certain matters that cannot fail to be of benefit to the business.)

AUTO GAS POISONING.

A Real Danger That Has Not Yet Received the Attention It Deserves.

From Lester Curtis, M. D., Illinois.—It is surprising that so little attention is paid to the toxic action of the exhaust gases of gasoline cars. Few of my friends seem to know or care anything about the matter. It is scarcely referred to in any of the books of my modest automobile library or any other such books that I have seen. The only mention of the subject in the popular prints that I know of, was a short article by the medical editor in a recent issue of a Chicago newspaper. Yet serious accidents from these gases are of frequent occurrence. Not long ago a Chicago physician was found dead in his garage from these fumes. This man was presumably intelligent but he was so imperfectly informed of the danger or so little impressed by it that he lost his life in consequence. Not long after this accident another physician working in his garage "noticed that the engine of his own person was sparking poorly. He took heed, groped to the door, managed to turn the lock, and fell unconscious in the open air. Help was hurriedly summoned and an hour or two later he was on the road to recovery."

Many cases are reported of chauffeurs while engaged with cars, experiencing vertigo, fainting and nausea or even coma from which it was difficult to arouse them. People working in the cabins of gasoline launches, or about motor boats, aeroplanes or other gasoline engines, often have toxic symptoms—headaches, dizziness and so forth. These symptoms appear rather slowly and insidiously. They may not develop until after the person has gone into the open air, and they are persistent. A case has been reported of a patient who recovered from the immediate effects of the gas but became mentally unbalanced nearly a week later.

The gas discharged from a gasoline automobile is a complex substance whose composition varies with every change of speed, barometric pressure and many other conditions. It is therefore difficult of analysis. Whatever has been done along that line has been under regulated conditions of combustion. So far as I know, no attempt has been made to study the gas when the car was in actual use on the road. Nor has any attempt been made to analyse the effect of the gas on the organism. Our knowledge then is far from complete, but we do know some things; three gases at least are present; carbon dioxide, (carbonic acid gas), the vapor of unconsumed gasoline, and carbon monoxide. The effect of carbonic acid gas is well known. It suffocates not by its poisonous action but by excluding oxygen. Gasoline vapor causes toxic symptoms which are unpleasant but not fatal. The case of carbon monoxide however is quite different; it is a dangerous poison; it unites with the blood corpuscles and destroys them. In other words it produces serious structural changes in the tissues which may be fatal, and even if the patient escapes death, may result in permanent injury.

The Encyclopedia Britannica says: "Most (gasoline) engines at certain speeds discharge considerable quantities of carbonic oxide (i. e., carbon monoxide) into the atmosphere." * * * "Experiments have been made * * * which clearly prove that in some cases as much as 30 per cent. of the whole heat is lost in the exhaust gases by imperfect combustion." What proportion of this discharge is carbon monoxide is not stated, but undoubtedly it is very large. "The enormous increase in motor traffic makes it important to render the exhaust gases as pure and innocuous as possible * * * in the interest of the health of our large cities." Enc. Brit., Vol. 20, p. 37.

We have then the danger to the health and even the life of individuals who are engaged with gasoline automobiles, but when we see the crowds of gasoline automobiles in the shopping districts and gathered around the entrances to places of amusement, each one belching forth large quantities of smoke and poisonous gas, we can not but wonder what will be the effect on the health of that particular locality and of the city in general.

Further study of this subject is sorely needed. In the meantime what we do know should be as widely published as possible and should be better heeded than heretofore.

Let your clutch in gently; thus you will keep your tire bills down.

AIR LEAKAGE.

An Important Consideration In Gasoline Engine Efficiency.

J. S. V. Bickford in Autocar.—In almost every book or paper one reads on the design of gasoline engines one finds references to the leakage of air into the combustion space by way of the valve stems, but I have never yet seen any statement as to the amount of this leakage. I have only seen one reference to the total amount of leakage of air into a gasoline engine, and that was made by Prof. Morgan at a meeting of the Institution of Automobile Engineers some time since. He gave the figure for a quite new 40 h.p. Daimler engine as 2.5 cubic feet per minute. Now I know that this is not nearly as much as the leakage into a 14-20 h.p. Wolseley engine in good working order but not new; what the actual figure is I am not certain, but estimates, based on the measured engine vacuum running down hill at different speeds and the amount of fuel required to run such an engine unloaded, lead me to the conclusion that the leakage is between 3½ and 4½ cubic feet per minute. At any rate, I can say that a carburetor designed on the assumption that the leakage in such an engine is 4 cubic feet per minute gives entirely satisfactory results, and the engine when fitted with such a carburetor runs smoothly when unloaded, and there is no noticeable amount of soot from the exhaust. If, then, we assume that into a four-cylinder 90 mm. bore engine air leaks at the rate of 4 cubic feet per minute, it is interesting to enquire the source or sources of this leakage.

By actual measurement I know that a ¼-in. bore round hole under the influence of a vacuum equal to that noticed in such an engine running idle will pass only 10 cubic feet of air per minute. It follows that into a 90 mm. bore engine as much air leaks as would pass through a round hole nearly 3-16 inch in diameter under the influence of a vacuum of 20 inch of mercury. Or, put in other words, if we assume that we have 5-16 inch valve stems, such a leakage would require that all four stems should be very nearly 1-32 inch slack in their guides, and since such wear as this would, of course, be uneven it would probably mean that the stems would be something like ⅛ inch slack at the worst point; that is to say, they would be in such a condition that no one would consider the use of them for an instant.

As a matter of fact, I have actually measured the air leakage past a well-worn valve stem 5-16 inch diameter in a cast iron bush 2½ inches long, the valve stem being 2½ thousandths of an inch slack, which is about the slackness of the valve stems of my Wolseley engine after a year's use. I first of all tried to obtain a measurement direct on my carburetor testing plant, putting the valve stem on the careburetor flange, and attempting to measure the air delivered into a gasometer. The amount was, however, so small that leakage of the plant rendered the results hopelessly variable. I therefore adopted another method.

The intake branch of my testing plant is provided with a stop cock, below which is a bend carrying the flange to which carburetors to be tested are fitted. I noticed that when the cock was closed, the vacuum measured by the mercury gauge fell comparatively slowly. It occurred to me that if I noted the time taken by this column to drop from one point to another, I should have fairly accurate data from which to calculate the leakage. I therefore measured the capacity of the apparatus below the cock by filling it with water. This was exactly 1 lb. or 27.7 cubic inches. I then closed the valve stem bush with a soaped rubber pad and noted the time of fall of the mercury column, thus measuring the rate of leakage of the joints less the leakage through the cock. As this leakage would be the same whether there was valve stem leakage in addition or not, all I had to do was to deduce this leakage from that recorded with the valve stem in position to get the net leakage past the stem. The stem was washed in gasoline to remove grease. The amounts were calculated by assuming that the volume of free air in the bend at any moment is directly proportional to the absolute pressure in the bend, temperature being neglected.

It appeared that the maximum net leakage of this valve stem is only .02 cubic foot per minute, that is to say, as compared with the total leakage into the engine it is negligible.

The question then arises as to where the rest of the leakage into an engine takes place, and the most obvious answer is past the pistons. But the reader will probably say that, if the pistons fit so badly that they will pass 4 cubic feet of air per minute under the influence of a pressure from the outside of less than 15 lb. per square inch, they would be useless against the explosion pressure of 300 lb., and the compression would be negligible.

Last spring when I was overhauling my own engine, I found, I believe, the solution of this puzzle. Next time the reader has a piston out of an engine which has run more than 10,000 miles, let him carefully remove the upper ring and rinse the ring groove out with gasoline, being, however, careful not to scrape it in any way, and then let him examine the groove under a magnifying glass. If his experience is like mine, he will find that while the lower face of the groove is bright and clean, the upper face is coated with carbon.

Here, then, is the explanation. On the explosion stroke the pressure is on the upper part of the ring which is driven down on to the lower face of its groove, where, the surfaces being good, a good tight joint results; on the suction stroke the pressure is from below, and the ring seats on a scale of carbon providing ample room for leakage.

I suggest that, if it be desired to restore the slow running of an old engine, replacing the upper rings of the pistons is a much more promising expedient than packing the valve stems, and I also suggest to those who have noted improvement in running from the latter expedient to recall whether, in fact, they did not at the same time make some alteration to the pistons and rings. In the nature of the case, a man is very likely to overhaul his pistons when he sets to work to pack or replace valve guides, and he is apt to forget this and to attribute the subsequent improvement in the running to the part of the job on which his attention was specifically concentrated, i. e., the valve guides. Even if no alteration has been made to the pistons it is possible that he has adjusted the tappet clearances, and, as we all know, this alone has a marked effect on slow running.

The valve stem which I tested, was not in really bad order.

For Carbon Removing.

From A. K. Wheeler, Massachusetts.—I noticed in your valuable publication, issue of January, an article written by Mr. S. W. Scovell, entitled "A Good Carbon Remover." I wish to endorse Mr. Scovell's article, for I tried this out on my Maxwell "35-4" 1914 model car, and it works to perfection. I am troubled a great deal with carbon, and have to clean it out for every six or eight hundred miles of travel. It is very handy to get at, by removing the valve plugs and scraping it out. I can usually do this in 2 hours, but by using the wire dish cloth as recommended by Mr. Scovell, it can be done much more quickly and it is very much easier.

I cleaned out two cylinders at a time, removing the valve plugs, putting in a little kerosene, and putting in a piece of wire dish cloth. I closed the cylinders, and removed the spark plug wire so that the cylinders should not fire, and ran the engine for about ten minutes. I then removed the plug and took out the wire dish cloth, and found that the top of the cylinder and the ends of the pistons were perfectly clean and bright. The only places any carbon was left was around the valves where the dish cloth does not hit, but this is right in the opening where it is easy to take out, and I was able to clean all of the cylinders in that way in 1¼ hours.

This method is perfectly safe and harmless, and is the best scheme I have ever tried, and the knowledge of this is worth one year's subscription to your magazine.

For Rusty Rims.

From J. A. Hogg, Hawaii.—The following is the best "dope" for springs and rims I have ever used. Gasoline, beeswax and powdered graphite. About 8 oz. beeswax to 1 gallon gasoline, and 6 to 10 oz. powdered graphite; two coats on each leaf, allowing time for drying. If springs are rusty, thin out the above and paint the rim or spring and in about thirty minutes you will be able to knock the rust off with a hammer. This mixture is oil and water proof. It is the best "dope" I have ever used for rims, and out here steel will rust over night. I think the above receipt was in the American Machinist. I keep a pot of it in the garage, and all threads and nuts have a little put on, and I know we will always be able to take them off again easily. I have received so many valuable hints in your periodical that I hope the above will help others.

Gasoline Storage Dangers.

From E. F. Sult, Colorado.—In your May issue, page 57, Mr. Walter L. Wadger, chemist, of the Massachusetts Police, shows the dangers of handling and storing gasoline. To me the article is not altogether clear. Are we to understand that the danger of handling gasoline may be avoided by not using any insulating material, such as chamois skin or wood? I think the article should be made a little more clear as the matter of safety is of vital importance to every owner and user of an automobile. I believe you will serve the best interests of your numerous subscribers by giving them a little more light on the subject.

Note by the Editor.—We concluded from the article referred to that if no insulating material was used in handling gasoline, and care was taken to avoid frictional electricity, that it was practically safe, especially if the gasoline was stored under ground. At this time we are unable to secure any further information on this subject, but hope to do so before the next issue is printed.

Easy Starting for the Ford Car.

From E. H. Thompson, Ohio.—I have just solved a problem similar to that of question 1608 in the May number. I have 1912 Ford with K-W master vibrator and have had no end of starting troubles for six or eight months past. First, I adjusted the float until the supply of gasoline in the needle valve chamber is slightly below the top of the small cup at the bottom of the chamber. This improved matters some but did not end my troubles. Next I discovered that the ball socket joint connecting the actuating rod to the rod at the foot of the steering wheel was worn so much that the spark lever could be moved several notches without changing position of timer. Placing the switch on the batteries, I moved the timer, retarding the spark, until contact was made, indicated by the buzzing of the vibrator, and lenghtened the actuating rod until with the spark lever in the fourth notch the timer would be on contact. Then I dressed off the ragged edges of the vibrator points and adjusted them with the engine running until all cylinders fired regularly and smoothly.

It now starts with one turn of the crank when cold, a quarter turn when warm and often on compression. A new ball socket joint and enlarging the actuating rod at the connection with the timer to take up the wear there will put it in first class condition so far as starting is concerned.

Opinions Differ.

From M. A. Foster, Arizona.—I notice in your April number, that Mr. Sleeper of New Hampshire, appears to have taken some exception to my reply to Mr. Archer of West Virginia. Mr. Sleeper appears to think that I am knocking the Metz car, which I am not. But I will say that the Ford is superior to most any car, regardless of make and price, for negotiating the mountains of Arizona. I have passed cars that cost twice that of the Ford car on the mountains here in Arizona. The large and heavy cars cannot climb with the Ford; neither can the friction drive climb with the Ford. They may do it with a new friction installed, but I doubt it. I have often seen the friction driven car stalled —not the engine—but the car, on account of the friction drive not being sufficient to draw the car up the hill. Now when Mr. Sleeper thinks that a 20 per cent. grade in Arizona isn't any harder to negotiate than a 20 per cent. grade in West Virginia, this is ignorance on his part. He must remember that West Virginia is an old, settled state and that the state has a system of road work, while Arizona has only been admitted to the states a few years, and, to my knowledge, the state has never appropriated a cent for road fund in this section of the country, as this is government reserve territory, covering a distance of 95 miles. The government expends a small amount of money on the roads here every year, but nothing like enough to make good roads. While a 20 per cent. grade in one place is the same as 20 per cent. grade in another, the difference is in the road bed, which we are short of,

Digitized by Google

but usually find a ledge of rock projecting out of the supposed road bed.

And right now I want to tell you that the little friction drive don't get over them. The fault may be in the driver for all I know, but it is believed to be in the friction drive. Now I stated in my article to Mr. Archer, that if the Metz car back in West Virginia was superior to the Ford car, they must have a new breed that we did not have here. I can furnish Mr. Sleeper with the evidence as I have stated, and believe that a hill climbing contest could be arranged very easily here, which would settle all disputes as there is no argument on the subject here in Arizona. Now, on the square, Mr. Sleeper, don't you own a Metz car?

That Hudson Car Clutch.

From A. D. Lent, New York.—In one of the queries which you published some numbers back and to which an answer was given it appears that one of your correspondents has had trouble with the clutch of his Hudson "33" (1912). The clutch let go only with difficulty so that low gear could be thrown in, in starting only, after considerable clashing of the gear teeth. You advised using thinner oil so that the disks would not adhere. I had a similar difficulty with my car of the same make and year, and I tried using thin oil but without success. I finally found that there was a small set screw projecting from the inside of the fork of the casing which carries the transmission and against which the lower end of the clutch throw-out lever abuts when the foot-lever is pushed forward in order to throw out the clutch. I screwed in this set screw one or two turns so that the foot lever could be pushed forward further than before. After this I had no further trouble.

Some Good Points.

From Dr. F. W. Boots, Illinois.—In the April number of your magazine J. N. Bagley of Nebraska tells us that storage batteries using a sulphuric acid electrolyte are made up of zinc plates. This is new to me, for I have always been informed that the plates are either of metallic lead or of litharge pressed into grids of metallic lead. Does any storage battery use plates of zinc?

In the trouble department of the April issue, M. R. Chappell of Colorado tells of his Studebaker missing on direct drive at a speed of 20 or 25 miles, especially on open throttle. I believe that his only trouble is a weak magneto, probably low voltage from weak magnets. A spark so weakened will ignite the richer charge of gas obtained by a closed throttle, but the leaner charge of gas which an open throttle should give for the unusually speedier engine requires a much hotter spark, hence his missing. If he will pull the cable from a plug while the engine is running, and allow the spark to jump from the terminal to the engine, he will find that the gap it will bridge is only a quarter inch or less, while it should be a full half inch.

I find that chloroform is greatly superior to gasoline for cleaning rubber preparatory to patching punctures and the like.

Note by the Editor.—Readers will much appreciate the foregoing. Concerning battery plates, they are sometimes made of zinc composition.

For Bad Weather.

From Reader, New Jersey.—I am no lover of wind screens. In fine weather, the exhilaration of a drive seems doubled if the car have no screen; the wind pressure seems to pump oxygen under pressure into my pores when I face the unimpeded gale. In bad weather, the raising of a screen and hood almost invariably creates draughts, and I reach home with a crick in my neck, or threatenings of pain in a stopped tooth, or the like. Hence my present car is hoodless and screenless; in their place I normally wear a big oilskin coat, and a similar make of storm helmet always lies handy under the cushion. Last month I was regularly trapped for a supreme test of my theories. I was compelled to drive ninety miles in the teeth of a cold rainstorm not unaccompanied by driving winds; and I had never a soul to speak to. I reached my destination dry, warm, but uncomfortable. The driving rain had inflamed my face, though the rest of my anatomy was cosy; and the soft skin round my eyes was pulped red. I cannot think that the genuine long distance all-weather man will ever take very kindly to hoods and screens on light cars unless draughts can be eliminated more successfully than at present; but, beyond question, the head needs some protection in really bad weather; and the eyes are the most vulnerable item in one's face.

In cold weather there are two expedients: One is the low, narrow panel of wire gauze, beloved of racing men; the other is an extremely ugly notion which a commercial traveler showed me during the aforesaid storm. Much experience of stiff necks and dental neuralgia had inspired him to devise a narrow celluloid curtain, which depended vertically from the front edge of the peak of an atrocious cap. The affair looked appallingly ugly, but it shielded his face and was transparent.

Who Can Tell Him?

From a Reader, Nebraska.—Does the editor of this department know of any device that can be attached to a pressure feed gasoline system, which will allow the keeping of a constant pressure from a motor driven air pump, but which will at the same time prevent excessive pressure in the fuel tank. These excessive pressures are caused by the expansion of the gasoline when driving in very hot weather. Two pounds pressure in the tank gives good results. Four or five pounds is entirely too much. It appears to me that a small spring controlled relief valve might possibly do the trick. The tank is located under the front seat where it gets the benefit of lots of heat from the engine. Therefore the aforesaid expansion.

An Improvement Suggested.

From G. W. B., Connecticut.—I have had the stem on a four point differential spider break and cause trouble and expense. I beveled the four ends and then when assembled peined the housing over the bevel to hold it in case of breakage. I took down another make of car this past winter and found the same conditions. I took out the spider, beveled the ends, and when put in place hammered over the housing. If the stem breaks at the base it cannot get out into the gears. The makers should overcome such a point.

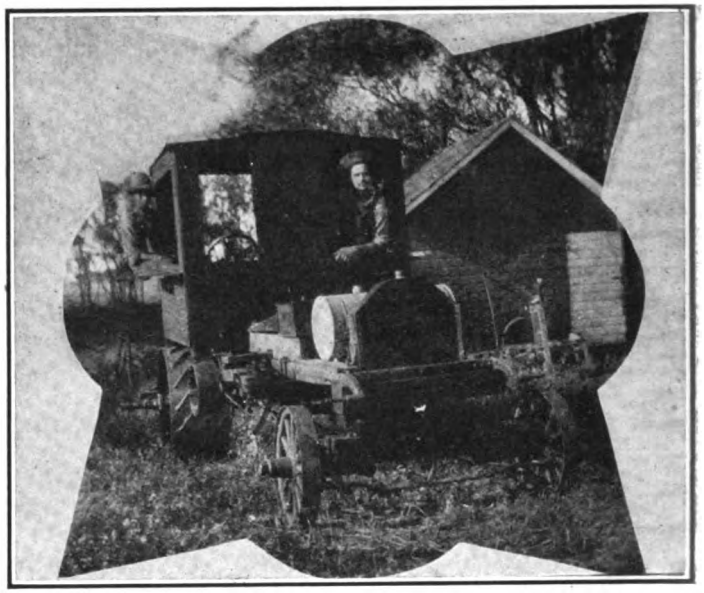
Making the Fuel Efficient.

From Reader.—To No. 1597 I would add that I do not know what the material is that he mentions but a small amount of high fire test cylinder oil added to the gasoline will very often add power. This it does not by making the fuel more explosive but by better oiling and packing of the piston rings at the upper portion of the stroke where the pressure is greatest and the loss fastest and where the cylinder usually gets less oil than it should. Practically everybody tries to keep the quantity of oil used as low as possible to avoid fouling of the spark plugs and accumulation of carbon, and every hard pull is likely to burn off and push away the oil that should remain on the upper walls of the cylinder. The result is gas leaking past the rings and the loss of power both by lost pressure and added friction. A very small amount of proper oil with each charge of fuel overcomes this. That there is a well recognized need for better results at this point is shown by the number of piston rings offered, all of which promise to hold the pressure. Many engines get so dry at the upper end of the cylinders that they pound on every hard pull. I have used and sold oil to be mixed with the fuel for many years and speak from a long experience. But many people fail to find the result desired because they do not use a proper oil. The oil must be of very high fire test or it simply vaporizes and instead of adding power it interferes with the proper proportions of the mixture and lessens power. Many people are using a cylinder oil of such low test that it does this very thing. It works fine so long as they keep their engine running fast. But let them pull the engine down to a slow speed and it lies down at once. The oil on the cylinder walls vaporizes so fast that the mixture becomes overfast while being compressed and either will not fire at all or if it fires it burns very slowly and with little power. In my humble opnion the only oil for a gas engine is one having a very high fire test.

For the Metz Car.



From W. H. Horner, New York.—Your answer to No. 1575 W. E. T., Maryland, should be to tell him to put in new Metz and only Metz piston rings, if the compression is any way poor, and a Holley carburetor, the same as on the Metz 1912, 4 cylinder runabouts. There is no spring or clutch on the Metz. Tell him to get a blacksmith to make him, out of ⅜ by 1 in. iron, two pieces the same shape as the clutch cross member, and bolt them on to reinforce the same, as they get weak after using a short time. I hope you can understand from this rough sketch what I mean. The Metz guarantee their fiber friction to last 3,500 to 5,000 miles. I have run my 1912 over 12,000 miles and the fiber is still good, because I have no slips.

For Radiator Cooling.

A reader says he has seen in some publication an arrangement described which was called a condenser, and which attaches to the filling cap of a radiator so that the funnel portion of the condenser faces forward, thus constantly allowing cold air to condense the water vapor and thereby increasing the radiator efficiency. Will any of our readers give the name and address of the manufacturer of this device?

His Gasoline Tractor.

From E. A. Klerrig, North Dakota.—I enclose a kodak picture of a gas tractor which I made out of a Peerless car. I have 18 horespower in the belt and on the draw bar. It has three speeds, varying from 2 to 8 miles an hour. It will pull a 12 inch triple gang plow in stubble, and haul hay and grain on the road. It grinds feed and cuts silage. It is not a very attractive machine but it does the business. If any

Mr. Klerrig's Motor.

reader has a Ford or some other light car I would be glad to trade some horses for it, as they are cheap and I am overstocked. However, I will not sell for a low price.

A New Hat Ready.

From J. L. Allen, Kansas.—To C. A. Stone: I saw your article about bracing the Metz car. I have one and we have always had trouble with our car and never could tell what was the matter with it until I saw your article. I have braced my car and now it works fine. I thank you a thousand times. If you will send me your address and size, I will send you a new hat, for I have burned up gas enough in a few miles to buy several hats.

Carburetor for Each Cylinder.

From G. W. B., Connecticut.—As some cylinders have more compression than others, I have often thought that some motor builders might try an individual carburetor for each cylinder. It would be much smaller, but it could be set to meet the requirements of each cylinder.

That Ford Car Knock.

From Walter Sanders, Wisconsin.—As I am one of your subscribers and take great interest in your journal, I will endeavor to write and tell you where I think the knock in the Ford car owned by W. H., of New York, is. I am a repairman myself and had the same experience. If I'm not mistaken he will find it in the front cam shaft bearing. The bearing no doubt was too tight in the first place and it cracked and parts of it fell away causing this bad knock. December number, page 49, No. 1471.

MAGNETIC INFLUENCE.

Hidden Force Discovered in Two Pole or Series Spark Plugs for Two Point Ignition.

In a series, or double pole plug producing two point ignition in a cylinder, to secure effective results the current must be entirely free from any undue influence, in its travel from one spark to the other. M. T. Minogue, the originator of two point ignition produced by spark plugs, who has spent several years time experimenting and perfecting the double pole or series plug has discovered a hidden force that has been heretofore detrimental to perfect ignition in spark plug two point ignition, and is explained herewith.

Two conductors each parallel to each other imbedded in an insulated member, the current passing down one conductor or electrode, as it is commonly called, jumping the gap to the other electrode on the inside of the combustion chamber and passing directly out again through the same insulation, and thence to another plug, sets up an agency known as static currents that causes a magnetism surrounding the insulation which clogs and greatly diminishes the current at the spark gap. In some cases where this condition arises to a high degree, the current is entirely choked from the sparking points. The current instead of being strong, forcible and hot at the spark gap similar as that obtained in a single plug is greatly minimized and causes the motor to skip and act in a very bad manner, because there is not enough of strength at the firing points in the current to properly ignite the gases, especially when a motor is running at slow speeds. Very frequently it occurs that it is impossible to get a motor to throttle down properly as it naturally would if it received its full volume of spark at the sparking points.

Many motorists using a series plug for two point ignition who had the experience that is herein related, have tried various means to overcome this annoying difficulty of weak firing and missing thinking that the trouble was in their carburetor or spark coil or else that their spark gaps were too wide and that their magneto was not strong enough to jump the resistance of the two gaps in both plugs.

The resistance of the two spark gaps in a series is so little that it can scarcely be noticed upon any make of magneto, providing that it is free from any choking or magnetic influence that is set up in its travel through the circuit. This can be plainly demonstrated by placing several plugs in series and it will be noticed that when the current is switched on that unless the battery is extremely strong, it will not spark over three or four plugs connected in this manner, but by eliminating this damaging influence to the path of the current passing from plug to plug, a dozen or more plugs can be placed in series, and when the current is applied they will each show not only a spark at the gaps, but will show a strong, hot energetic spark. This plainly shows that the resistance of proper adjusted spark gaps is very small indeed.

This influence spoken about is not found in a single spark plug where the single electrode passes through the core or insulation and jumps the inside ground. This action of the current traveling through the insulated member and returning through same in a parallel manner sets up this condition which is something similar to the magnetic influence that is excited in a dynamo or generator when driven to speed.

Mr. Minogue has not only discovered this action as taken place in a series or two pole insulated plug, but has also discovered a means whereby the magnetic influence is entirely eliminated, which has been proven by late tests of the new construction, which will show a good fat spark on a dozen plugs at each gap, while before eliminating the static influence from the plugs the current would entirely quench with only four plugs in series, also its effectiveness is proven in the perfect ignition of the motor at all speeds.

As two point ignition is now being so largely used, this discovery will be of great interest to those who are using two point ignition.

WELDING PRACTICE.

How to Handle Broken Parts of Automobiles and Other Machinery.

From J. N. Bagley, Nebraska.—A few years ago welding machines were found only in the larger

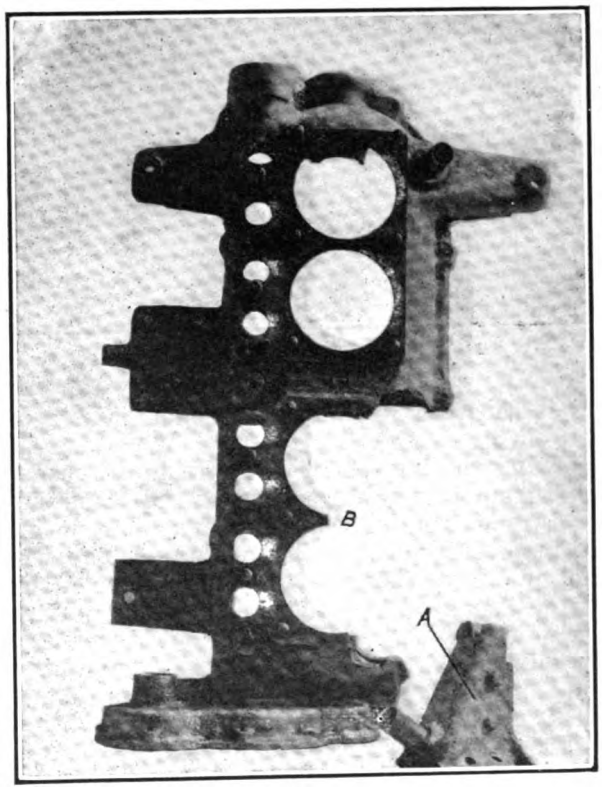

Fig. 1.

cities, but to-day we find them scattered over the country and in many of the smaller shops. Repairmen have begun to realize the necessity of the machine as well as the profits derived from it. No time since the welding machine made its appearance has there been such demand for the skilled operator, as a man who can handle the welding machine can get work much quicker than the man knowing nothing about it. An experienced operator can handle almost any kind of metal with success such as broken cases, crankshafts, machine castings, etc.

In the spring there is all sorts of planting machinery with broken castings, which can be fixed at a very good profit to both the farmer and the operator. A little later on or soon after comes the cul-

Digitized by Google

tivating time and a different kind of machinery is brought into play and this must be repaired as well. Then after this come the time of harvest or the busy time, as we call it in the West, when every machine that can harvest grain is brought into use. When one of the harvesting machines gets out of repair on account of a broken casting, the farmer

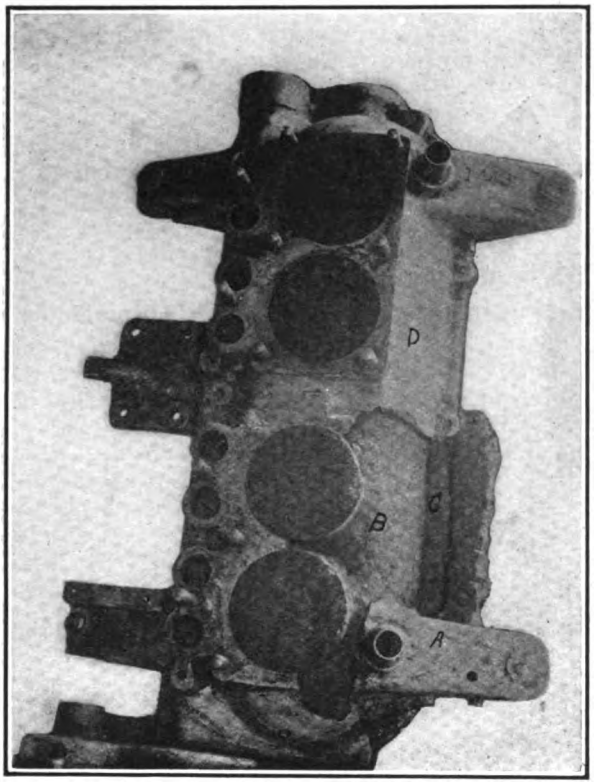

Fig. 2.

wants it repaired just a little sooner than is possible to do it.

Following the harvest is the threshing season, to get the grain into the bins before fall rains set it. The only man able to keep such machines in order is the man with the welding machine. The writer has had many welding jobs come a distance of thirty miles for repair in a busy time, and by having a machine to do the work, the advertisement was worth much in after years. Next in rotation will be the fall plowing and seeding which is generally crowded along as fast as possible for the plant to get a foothold before winter closes in, and at this season of the year we find the welding machine very profitable. We have been the round of the seasons and find that every one of them demand different machinery, which must be kept in repair, and the welding machines will play an important part.

Now what are we going to do with the welding of broken parts of automobiles, which are used nearly all the year around? Stop and think a moment and figure, if your shop will not afford a machine at the price they can be purchased for at this time, and good ones, too.

Difficult to operate? Not a bit more so than your lathe, your vulcanizer and a dozen other tools about the shop. It just requires a mechanical fellow, or to put it plain, a man with ideas. When a lathe job comes to the shop no matter how difficult to chuck or hold, we manage somehow to get the job done in very good shape. The same with the welding machine. The job may look a trifle hard or impossible, but if you have ideas and put them to use it will surprise even your own self how successful you can be. The writer never saw a welding machine until a few years ago and that was a home-made affair, and he never had a lesson from an instructor, but he gets on very well. Of course, some of my early jobs were not good. Now and then one would be a failure entirely. Nevertheless, I kept at it, learning a little from time to time until I was as successful as the average.

Aluminum at first was a sort of a bugbear with me, and I would send my work of this kind away to have it done, but one day I thought I would make an attempt, and luckily it proved a success. From that time on I kept all my work at home and got it out in some manner, but it all passed. I told my customers I was not an expert but would do my best and if it broke would do it over free of charge. Of course, I had some to do over, but by so doing I "killed two birds with one stone;" I got the experience and held my customer.

Fig. 1, shows a case from a Buick car, as it was brought to the shop for repair. All the pieces, save the support, were gone, as the customer when he saw what happened was angry at his ill luck and had left them lying in the road. I was not exactly decided as to how I would get the job out, but after

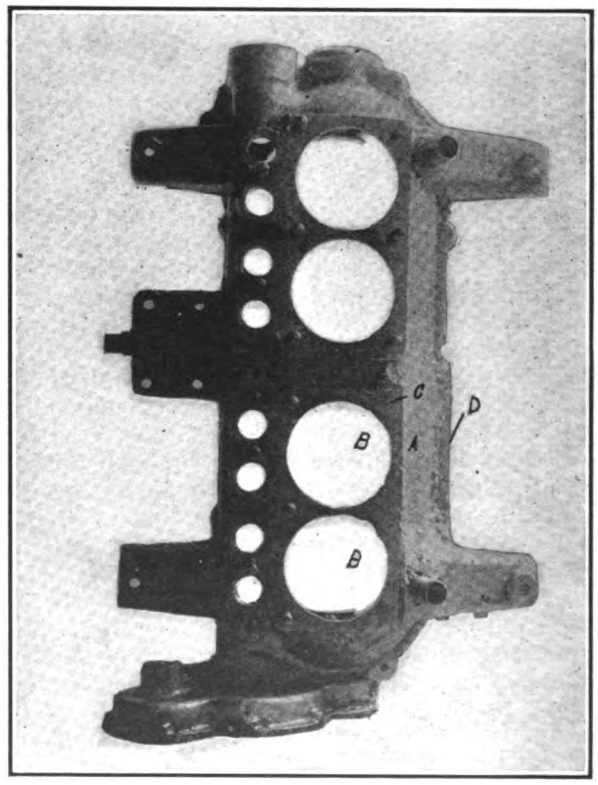

Fig. 3.

spending some little time thinking the matter over, I decided to try it. The arm A, was all that I had to build to, as all the parts, as at B, were lying in the road many miles away.

Fig. 2 shows the job well under way. The case was placed on a level surface and the interior of it at B was filled with moulding sand and shaped up to the exact shape of the case. Bringing the sand

Digitized by Google

to a line with the interior of the case acted as a core for the metal that I intended to pour. At C, was a cored place for a rib to bolt the pan to, as it was entirely gone. Now with a piece of light black iron I formed a piece that would take the outside shape of the case and fitted it carefully over the case, leaving a place at the extreme top for a funnel

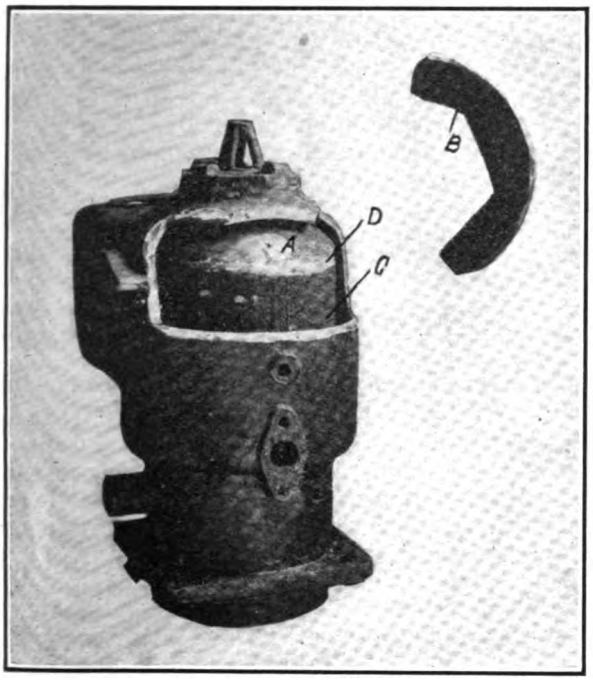

Fig. 4.

to project into the opening between the core and the cover. After the metal cover had been placed and shaped I covered it over with moulding sand, building up well around the funnel. I melted the metal and poured it into the funnel, having a sufficient amount to leave the funnel full after filling the case. This is a necessity to hold the metal close so there will be no bubbles or coarse places in it. After pouring I left the job in this shape to cool, and every once in a while I would come over and take a look and wonder how it would look when it came out. When I took it out I was surprised to find a very good side in the case, and all there was to do was to weld up the joints that were left where the new metal came to the old, and the job was done, except some filing and drilling for the studs to hold the cylinders to the case.

Fig. 3 we have the case when it was finished except the drilling of the holes as mentioned. The edges of the openings B, were a little rough but were smoothed with a large half round file, C was a little high and I cut it down with the shaper A, the new side, which needed no dressing or filing. The added part D, needed a little repair or rather dressing where it fitted to the oil pan but all this required very little time. This job has been in use for some time and has stood the test well. Since this experiment I have repaired many cases with good success and it never bothers me whether or not the pieces are all brought along. In welding work of this kind I never remove the core as I call it until all the welding is done from the outside. When the joints are all welded I remove the sand from the inside and place it in the oven and heat it up to prevent cracking and weld up the inside and place it in the oven and close the drafts and kill the fire and leave it to cool. If preferred it can be left to cool in a box of air slacked lime which will prevent the cold air cracking it.

Fig. 4 is a job I considered a trifle difficult in my earlier experiences. It is a cylinder which has been broken at the combustion end because of a piston being driven through it. The crack at A, runs about three inches around the head and it was necessary to remove the portion of water jacket as shown. The part B, was cut with a saw and lifted out of the way after which the crack was ground with the wheel until a large V notch was its entire length. The interior of the cylinder was filled with moulding sand and the entire heated until it was almost red when the crack was welded at D. As soon as welded the water space was filled with hot sand and the jacket B placed back in position which had been previously ground to a V along the edges. The part was welded in and the entire cylinder buried in lime to cool. After it was cooled it was ground smooth and placed on the car as soon as the sand was washed from the water jacket. This cylinder was just as perfect looking as the balance of the cylinders and could not be told from them. It has been in service for many months and shows no signs of weakness.

Fig. 5 is the body of a spray pump, a very simple job to handle. The crack at A, being about 8 inches long, extending in a curved direction around one end as shown. This was ground almost through with a thin wheel leaving a place for the filling with the filler rod. The inside of this case I packed with sand and heated the entire piece to a dull red after which I buried it in the lime to cool. I have found that where the sand can be used and the entire mass heated together, the air has less chance to get at it and the sand holds heat. Consequently a

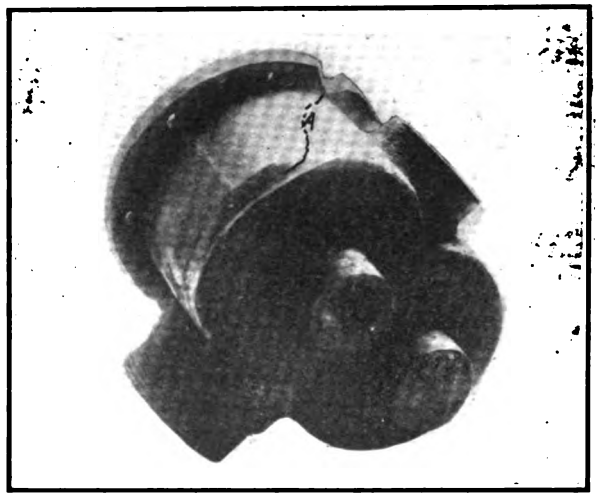

Fig. 5.

long crack will not take as much gas as without the sand, as the larger the body the slower the heat will radiate away. Aside from this there is less chance for a casting to warp. There is some little knack in keeping the filler rod soft enough to be filed after it has cooled in place. This is hard to explain or describe but can be found by experience. The flame should be played on the rod frequently above the crack and keep the rod almost a "mush," as we call it, so it will seem to flow from about a half

Digitized by Google

inch off the end of the rod. This prevents air bubbles and makes a better job. After the temperature has dropped a trifle and the torch is turned back on the weld it will nearly always leave a few air spots in the work which may not do any particular harm, but it makes the work look a little rough.

VALVE LIFT.

Claims it Has Nothing to Do with the Running of the Engine.

From J. F. H., England, in Motor.—The question of degree and duration of valve lift appears to have attracted some attention of late, and the suggestion has been made to employ a camshaft with variable cams as a possible solution of the problem of providing an engine which shall combine the advantages of the slow-running engine of low mechanical efficiency with those of the high speed engine of maximum mechanical efficiency, both of equal volumetric measurement.

Apart from the doubtful advantages of increasing the mechanical complications of an engine by incorporating a movable camshaft having cams of varying degrees of lift, it appears to the writer that such an arrangement is rendered quite unnecessary in view of the fact that the lift of the valve adjusts itself automatically to the requirements of engine speed owing to the inertia forces of the valve mechanism, which are at all times proportionate to crankshaft revolution.

In all engines there is a critical point in speed at which the tappet roller ceases to follow the cam profile closely, and thereafter the degree of "bound," if it may be so termed, is commensurate with the rate of increase in speed, and this is why, in the writer's opinion, any proposition to vary the lift of the valves by mechanical means is altogether unnecessary. If it were logical to assume that the tappet roller follows the cam profile closely at all speeds, then there would be sufficient reason for the suggestion to vary the valve lift mechanically up to the point beyond which varying the lift ceases to have any effect, but in view of the inertia forces set up by accelerated motion, there does not appear to be any necessity for the adoption of a device of the description suggested.

In the opinion of the writer, assuming the valves of an engine to have the correct degree of lift, and the gas passages to be proportionate to cylinder dimensions, the effect of varying the degree of valve lift mechanically would be merely equivalent to that of throttling the gases in the orthodox manner. Assuming an engine to be of maximum mechanical efficiency, then the whole question would appear to rest upon a determination of the correct degree of valve lift in proportion to gas passage area, and, when this condition is fulfilled, no further increase in lift can have the slightest effect on the speed of the engine; the maximum effective lift of a valve covering a gas passage, say 2 inches in diameter, is ½ inch, and nothing would be gained by increasing it; in actual practice it is not customary to go to the maximum.

Therefore, it will be obvious that, if the sluggish engine is sluggish with correct valve lift and throttle fully open, it will remain sluggish to the end of its days; the only possible means of putting "life" into it will be by advancing the ignition. Beyond this its case is hopeless; its sluggishness is entirely determinate upon and co-equal with its degree of mechanical efficiency, and this latter feature it is not possible to alter.

The "lively" engine can at all times be toned down by throttling the gases and retarding ignition, and it is difficult to see wherein lies the difference between throttling the gases in the gas passages leading to the cylinder and throttling them in the cylinder itself by means of varying the valve lift. The question resolves itself into one of giving proportionate power at all speeds; that is, no falling off beyond that which must naturally follow reduced speed, and no mechanical arrangement for varying valve lift can possibly be necessary or beneficial when we have already at command acceleration and deceleration by means of throttle and ignition control.

EXHAUST VALVES.

How to Keep Them in Good Condition for Satisfactory Service.

As the result of improvements, an average distance of 1,500 miles can be covered before the exhaust valves of an automobile show signs of requiring attention, and there are doubtless many instances of much greater distances having been covered without the valves having been taken out. It is not advisable, however, to leave the valves without attention for an indefinite period, and after every 1,500 miles they should be taken out and examined. It is much easier to deal with a valve if it has not been left to deteriorate to any marked extent than it otherwise would be. In the former case simple methods of treatment will suffice, whereas if a valve has been neglected so that it has got into a bad state it cannot be dealt with except in the lathe and by the use of special tools to cut a new surface on the valve and possibly also on its seating.

Concerning the actual details of grinding in a valve it is not necessary to repeat these, as the manipulation is such common knowledge; it is, however, proposed to refer to some of the points which are liable to be overlooked or insufficiently attended to.

It is important when the valves are taken out that some sort of test should be made to see whether they are approximately true and concentric. This applies more particularly to the exhaust valves, subjected as they are not only to the mechanical shock of operation, but also to the intense heat of the exhaust gases. The tendency to warping is considerable at that part of the valve stem just below the head. A properly designed valve is intentionally made much stronger at this point than elsewhere, and it should not warp appreciably if the engine has been run normally, but if otherwise, and the valves have been severely overheated, even the extra strong "neck" provided may fail to keep it true.

If a lathe is convenient, valves can be easily tested for accuracy between the centers. Failing this, the condition of them will have to be tested with a straight-edge, or better still, a gauge cut out of sheet metal so as to fit close along the stem, neck and head of the valve. Once made, a gauge of this sort can be used indefinitely with the same set of valves, and with a little practice in testing a valve

Digitized by Google

at various positions the slightest inaccuracy can be detected. The truing of a valve stem is best done by pressure and not by hammering, which is liable to do more harm than good. With suitable grooved blocks of metal, or even hardwood, and the pressure obtainable between the jaws of an ordinary vise, it is a simple matter to "reset" a valve by applying the pressure at a proper point, and thus forcing back the stem where it diverges from a straight line.

There is no doubt that many engines are run with the valves defective as regards this matter, and consequently not only does the valve never obtain a proper seating but a great deal of unnecessary wear is caused on the valve guide. This worn condition explains why so much oil leaks down the valve guides of certain engines. Grinding-in should be done intelligently, always keeping in view the fact that it means a certain amount of wear on the valve and seating—especially the latter—every time the operation is performed. It is, in fact, not unusual to find that the grinding-in has been so vigorously and so frequently done that the valve has sunk well down into the seating. If it be found that the valve face has some unusually deep "pit" marks in it, the better plan is to have the valve refaced in the lathe or by the use of a valve cutter, otherwise by the time the marks are ground out the seating will have been worn to an excessive and disproportionate degree.

A point which does not as a rule receive attention is that of preventing the abrasive material used in grinding from reaching places where it can do harm. The tendency is to use far more of the abrasive material, such as emery or carborundum, than is necessary for the actual operation. The surplus amount is very liable to reach the valve guides, and possibly also the cylinder, as the abnormal marks or scratches sometimes found on the cylinder surface indicate. A precaution against this taken by careful operators is to pack some cotton waste into the port and below the valve head. Failing this, great care should be taken after the operation thoroughly to clean all around the valve and down the guide with a paraffin-moistened rag to clear away any trace of the abrasive material. Finally, should it be found, after say 1,500 miles of running, that the exhaust valves get into a bad state and show signs of intense heat, the surface showing what is termed "scaling" or flaking, some abnormal circumstance in the running may be suspected, such as faulty carburetion or water circulation, or it may be a throttled silencer, and this should be attended to.

Efficient Piston Rings.

From N. G. Near, New York.—Here is a test that every efficient piston ring should be able to

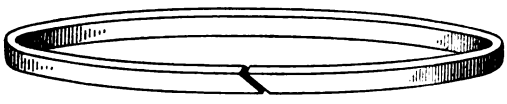

Fig. 1.

stand: Take the ring, or any part of a multi-part ring, in normal shape as it appears in Fig. 1. Pull it apart as in Fig. 2, twist as in Fig. 3, and compress as in Fig. 4. If suitable for its work the ring will spring right back to its normal shape, Fig. 1. Any ring that takes a set under one or all of these three tests has not the resiliency to stand its insertion on the piston and best adapt itself to a perfect fit with the cylinder wall. Even if rings sprung in handling do not break, they are apt to leak. A good way to distinguish between good and bad metal used in piston rings is to break the rings and compare the crystalline structure. Coarse grain indicates an inferior metal, utterly wanting in flexibility. Too often, unfortunately, piston rings are made of this

Fig. 2.

"pot metal," consisting of scraps melted together and cast into long sleeves from which the rings are machined one after another. Such rings frequently break in being put into place, and even if not they are unable to stand the twist without permanent internal strain.

Close, fine, uniform grain of specially processed gray iron is now used in the best piston rings. Any

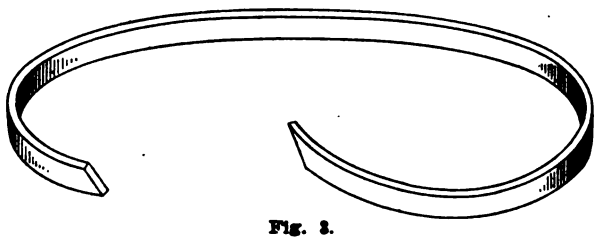

Fig. 3.

metal expert will tell you that these fractures indicate extreme resiliency, immunity to distortion in assembling, hardness to assure long life, and that the fine grained metal does not deteriorate so quckly under even the high heat from the combustion as does the coarser grained structure. These characteristics and assurances of correct service are pos-

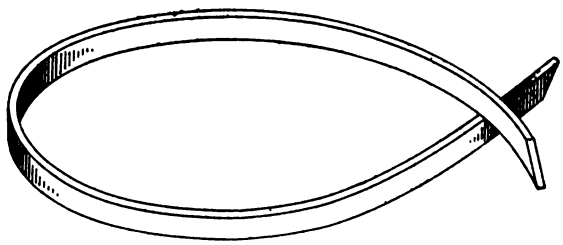

Fig. 4.

sible in the highest degree only by making each ring or ring part an individual casting. Each part must then, of course, be machined, ground, and tested separately. There must be no slip-shod work.

In ordering rings for a given motor it is always well to state the make and model of car, number of rings wanted, bore of cylinder and width and depth of grooves. Sometimes it is a good plan to send a sketch giving all dimensions.

Piston rings should fit their grooves with only enough ease to permit free seating without lateral motion. Much used pistons in which the grooves have widened should have their grooves turned up 1/32 inch wider than the original width and correspondingly wider rings should be selected. Such machine work, however, is seldom necessary.

Missing Numbers—Our Readers are requested to remember that it always gives us pleasure to re-send numbers which have gone astray in the mails.

The Automobile Dealer and Repairer in Australia and New Zealand.

Mr. R. Hill, Matlock House, Devonport, Auckland, New Zealand, is our accredited representative in Australia and New Zealand for obtaining new subscriptions.

ALL DO NOT RUN ALIKE.

It must not be assumed that all cars of the same model and made by the same firm run equally well or will give an equal amount of satisfaction. Even the highest priced cars of the same model vary in running quality and in expense for repair, and in the case of cheap cars this variation is often wider than would ordinarily be suspected.

Reference is not now being made to a variation that is due to a difference of care in running, but to a variation that is apparent from the moment the car is taken out. The fact is, no matter how comprehensive or careful the testing may be, both in the factory and when tested by the manufacturer outside, no car can be made that is an exact replica of another in quality of material and in size of parts. And even though there be a variation in but one particular, that variation may soon cause a more important variation in another part of the car that will result in no end of trouble and expense.

This fact is referred to for the benefit of occasional readers who express dissatisfaction with their experience with a certain car even when they have used it judiciously and intelligently, and who often send us complaints against that particular make of car, when in nineteen cases out of twenty it gives the highest satisfaction to other users.

We have in mind one of the best runabouts of a medium price that is made. The man who owns it is a good driver and a careful driver. Yet he has had so much trouble with it that he has decided to dispose of it at a much reduced price. On the other hand, we recall a woman who owns a car of the same kind, year and model which she has driven 5,000 miles without spending a penny for repairs, and the self-starting system is so perfect that the car has never been cranked.

The foregoing conditions might be expected in the case of the low priced machine-made cars which it is impossible to thoroughly inspect and test, but it can hardly be accounted for in the case of the medium priced cars which are far more carefully made, inspected and tested.

Before us lies a letter from a car owner advising no one to purchase a certain kind of car that he owns "unless he wants to have a car in the repair shop all the time." We chance to know that in this instance, the car referred to is generally giving the best of satisfaction, and it would obviously be a gross injustice to print the complaint the man makes.

It must not be assumed that this condition is a common one. But it exists, and it must not be overlooked. That the testing of a car at the factory before it is sold is most important, and that the running of the car by the purchaser is even yet more important, all goes without saying, but no machine as complicated as an automobile and composed of as many different kinds and sizes of material, can be expected to run exactly the same as all other cars of the same model. That two, or a dozen, or an hundred, or even a thousand medium priced and reputable cars may run so nearly alike that the difference will be scarcely perceptible, is usually the case, but then comes an exception where a car runs badly and unlike any of the others.

BEST FOR A TOUR.

A reader asks which would be the better for a trip from this State to the Mississippi River, an automobile or a motorcycle with a side car. He says he intends to take this trip next month with his wife and wants to go without unnecessary expense and as comfortably as possible.

Even assuming that his means are limited, if he can afford to take the trip at all, he should take the automobile by all means. The writer of this is no "'prentice hand" in touring. He has toured in an automobile, in a motorcycle, on a bicycle, with the Smith motor wheel attached to a bicycle, and—on foot. If distance is of no consequence and the recuperation of health is the aim, there is no better method of travel than by the means nature has given us, or what is somewhat uncouthly called "shank's mare." Sleep out-of-doors and under some pine tree, if you can. Next to this, and where distance is a little more important, the bicycle is a healthful and quite satisfactory means of locomotion. If you want to get somewhere quickly and at the smallest possible expense for a given distance, use a motorcycle. This is not exactly the vehicle for the fair sex, however, either with one as a passenger on the rear of the motorcycle or in a side car attachment. The side car is uncomfortable for a woman and the arrangement itself mechanically unscientific. It is well enough on level and smooth roads, when it comes to steep hills and rough roads or patches of sand first on one side of the road and then on the other, such riding is anything but easy or simple.

On the whole, we believe our friend will find the

Digitized by Google

automobile to be by far the most pleasant and convenient vehicle for his trip, and especially if he is to take his "better-half" along.

GASOLINE.

Let no one imagine that there is but one quality of gasoline on the market. There are as many qualities, almost, as there are qualities of cloth, and like everything else the best gasoline is the cheapest.

Although there is a wide variation in the quality of gasoline, this probably is not due to the different kinds of petroleum from which it is made, although this in itself varies widely. Pennsylvania crude oil contains from 1/8 to 1/5 of its volume in gasoline, while Texas and California oil contain only about 1/30. Good gasoline should have what is called a Baume test, or from 65 to 68 degrees, while high quality gasoline tests 72 degrees. The higher the Baume test the easier the gasoline is to start the car, and the smoother it runs.

In the vicinity of New York City gasoline is sold all the way from 12 to 18 cents a gallon, and as far as we can learn, no one can afford to sell good quality gasoline at less than 16 cents a gallon. A good test of gasoline, in the absence of a hydrometer, is to pour a little in the hand. When it evaporates slowly and leaves a little grease deposit, it should be rejected. When it evaporates rapidly and leaves the hand dry and clean, it is acceptable. Water is frequently present in gasoline and is liable to get into the pipes and carburetor. This, of course, impairs its quality. When filling a tank a strainer funnel should always be used. This keeps out the dirt and often prevents a trouble that is hard to locate. Poor gasoline makes a car start hard and run sluggishly.

GRADE CROSSING DANGERS.

Grade railway crossing dangers are causing increased comment and apprehension—save among many automobile drivers who have the most reason to fear them. We get so sick of reading accounts of grade crossing accidents in the face of the constant warnings given, that we sometimes feel—paraphrasing the words of the Psalmist—like "saying in our haste" that all who meet with such accidents meet with just what they deserve. Or at all events, since our warnings seem to have no effect, possibly the creation of a bit of indignation at a sentiment like the foregoing may be impressive. One can sometimes afford to rest under the stigma of being heartless if it will have the effect of lessening a great evil of recklessness.

On Long Island, N. Y., where grade crossings are unusually numerous, the railroad has had warning signs put up, entreating drivers to "stop, look and listen" before attempting to cross a track. But railroad officials themselves are not blameless, by any means. If they were so disposed, gates could easily be placed before all such crossing where flagmen are not now provided. No one can justly ask that all grade crossings be at once removed, for that would be something that neither the combined resources of the State and the railroads could afford, but in remote localities where flagmen are not employed it would be easy and comparatively inexpensive to have gates automatically actuated by approaching and departing trains. Of course, if an automobile driver is so blind that he can't see a closed gate, even such a plan would not be effective.

The fact is, the railroads are naturally adverse to spending anything not absolutely imperative. Where damages for accidents would be more expensive they employ gates and a flagman, but in localities where accidents are comparatively infrequent, it pays better to settle than to make the crossings safe at even a small expense.

JUDICIOUS DRIVING.

Commissioner Goldwater of the department of health of New York City, has announced that he will ask the legislature of the State to pass a law requiring applicants for permits to operate automobiles to submit to what may perhaps be termed a "psychological" test of fitness. "The control of an automobile in the streets of New York," he says, "is no task for a child, an untrained amateur, a neurasthenic or an excitable person. In such hands it is an engine of death. Under the highways law the question of mental ability to operate a motor car is not considered."

No doubt the premises of Dr. Goldwater are correct but his conclusions are faulty. It is true that those afflicted with the defects he refers to are unfit to drive a car in the streets of New York, but a correct determination of such defects by an examination would neither be practical nor positive.

A far better plan, and one this magazine has invariably advocated, is to "make the punishment fit the crime." In other words, make the penalty for driving so that the safety of other users of the streets is jeopardized, so severe that no one will dare do it. It is easy enough for a policeman to know when such an infraction of the public safety is being made, but it would be impossible for a Solomon to accurately determine who would not under any circumstances drive in this way.

WELDING INFORMATION.

Any of our readers who would like information concerning oxy-acetylene welding or the various devices or outfits for welding by such means, are invited to send inquiries to this office. They will be answered by an expert, and such information will be forwarded by letter whenever desired, and afterward published in this magazine. Oxy-acetylene welding is comparatively a new art, and is rarely understood by the average mechanic, and it is felt that such a department will be of general interest to many of our readers. The use of the automobile as well as of much farm machinery has made welding an important adjunct to every garage and repair shop as well to the general machine shop. It may be added that answers to inquiries will be made in a simple way so that they may be easily understood by any one.

FOR SUBSCRIBERS ONLY.

It is hardly necessary to state that the information given in the Trouble Department of this magazine or by letter is for the benefit of our readers only. Nor will such information be given reluctantly or grudgingly. No matter how much time or expense it requires, we consider that our readers are entitled to it. But others who desire information should first send in their subscription order.

AUTOMOBILE PRODUCTION.

English and American Methods Compared and Explained.

From The Motor, England.—A few days ago I was escorting an American motorist through one of the largest of our motor factories, when he inquired what wages a man he saw looking after one of the machine tools would earn. I told him probably 10 pence an hour.

"How much is that a day?" he asked.

"Something under two dollars. I suppose in America the same man would get three times as much?"

"Why, yes; about five dollars a day." And then he added, "Say, this puzzles me. How is it, with such low wages, you people in this country cannot knock spots off us Americans on your prices?"

I told him we did not think the wages mentioned were so particularly low, when we compared them with the figures paid on the Continent. And this made him more than ever puzzled as to why the Continental firms could not wipe American manufacturers off the face of the earth in competition.

Many things in that factory surprised him. Some agreeably and some, I could plainly see, otherwise. A little later on we came to a man drilling holes in the bottom half of an aluminum crankcase. He was bringing the work into position under the tool and drilling each hole separately, one at a time. This astonished my friend immensely.

"My!" said he, "Why, in America they would do all that lot at once," and he asked how it was we did not do the same over here.

When I explained things to him a bit, he saw the point, and doubtless many others, unacquainted with manufacturing methods, may be interested in the explanation I gave him. Certainly, if the true inwardness of such things were better understood by the public, we should hear less of the newspaper tirades we occasionally get from insufficiently informed, but doubtless well-intentioned people, and from mere politicians, who cannot see how such things as tariffs, for instance, can in any way affect the conditions of an industry and when British producers appear to be losing ground against their foreign rivals, simply denunciate the manufacturers as being ignorant of their own business and behind the times in their methods, and shout to them: "Mend your methods and do not bother about tariffs, and you will be all right."

In this particular piece of work there were probably 20 holes to be drilled and the operations of centering the work under the tool and passing the drill through the metal, probably took three minutes. Now, here was a man doing each hole separately, and what my friend pointed out was that, whereas he was working with only a single drill, in America he would be working with a cluster of drills, each positioned to make its proper hole in the work, and, when the work had once been accurately placed for the operation, the whole of the 20 drills would be brought down together, the actual operation of drilling the entire 20 holes thereby occupying no more time than the man he was observing took to pierce a single one. On the face of it, of course, all other things being equal, the British manufacturer in whose works the observation was made was working in a most wasteful manner by employing methods by which it took a man a full hour to pierce those 20 holes, when, allowing for a little extra time, perhaps, in the first positioning of the work, with a different tool equipment, it could be done in five or six minutes. Indeed, my friend went into figures, and showed that, piercing these holes, one at a time and paying a man 20 cents an hour, the holes cost 1 cent (one half-penny) each to drill, and the labor on this entire piece of work cost 10 pence, whereas, if the man had been provided by his employers with such a tool as he would have to work with in an American factory, he would do the whole work for a penny, and, allowing for the wage rates in the States being approximately three times those ruling here, even there the cost would be but threepence, thus showing a saving to the manufacturer on the labor cost of this one item alone of over 2 shillings in America or 9 pence here, counting British wages. And he observed that this was only a single operation of the many hundreds of operations required in the production of a motorcar, so why we did not just pick up the pennies all around and fill buckets with them he could not understand at all.

The explanation I gave him was this: The firm in question, although one of the largest manufacturers in this country, was producing four or five different models of engine, making only from, approximately, 300 to 1,000 of any one type and averaging, perhaps, 600 of one particular model. Now, taking the latter figure for the purpose of calculation, I showed him that, whilst the machine-tool he saw working could be employed equally well in drilling the holes in the crankcases of each of the four or five models, such a tool as he had seen in American factories would require to be built specially to drill the holes in a single model only. This tool might, very possibly, cost 200 pounds sterling to install, and I showed him that, if installed and completing its work in, say, six minutes per unit, or allowing only five per hour, it would finish off in a fortnight the entire number of crankcases required in a twelve-month, and would, therefore, be lying idle more than eleven months out of the year, occupying space in the workshop and, so to speak, "eating its head off" doing nothing; whilst, allowing 5 per cent. interest on the capital and only 10 per cent. depreciation, without reckoning anything for its share of rent, of floor space, etc., the cost to the manufacturers would figure out at 30 pounds sterling, whereas the saving, even at 9 pence per unit, would be but 22 pounds 10 shillings; so that, on this calculation alone the manufacturer would be out 7 pounds 10 shillings. Further, as the tool was only capable of doing that one particular piece of work, if the next season's design called for an alteration in the part operated upon, the whole or a great part of the machine would be practically scrapped, to say nothing of the fact that, if he were to use such a machine, the manufacturer would have to carry his whole stock of crankcases through the year instead of spreading them over the period, thus locking up a considerable amount of capital, the interest upon which would have to be reckoned in.

Next I pointed out to him that, on a production of 15,000 per annum—which is quite an ordinary output of a single model for any of the leading American manufacturers—that machine could be kept steadily employed for the whole year. Whilst, at a rate of saving of only 7½ pence per piece, the gross saving at American wage rates over the

Digitized by Google

British method and wages would be 468 pounds, 15 shillings, an amount which would allow the tool, costly as it would have been, to be thrown away as scrap at the end of the year if need be and still leave the manufacturer over 250 pounds to the good, whilst the saving to the manufacturer at American wage rates would work out at something like 1500 pounds sterling.

My friend then began to see things in a different light, and remarked that it was evident from what I had said that the principal factor governing the situation was the quantity produced, on which I assured him that he had "hit it in once." Here is, indeed, the secret of the success of American methods in reducing the cost of production of the goods and at the same time paying a rate of wage several times that which pertains here. Indeed, it is this high wage rate which practically compels American manufacturers to adopt such methods if they are to compete at all with Europe. There is no mystery about it. And there is no ignorance, or backwardness, or want of enterprise in our manufacturers. They are producing by methods which, under the quantity and wage conditions under which they have to work, give the best results. Apart from the fact, however, that American producers of motorcars have the largest market in the world all to themselves, tucked in safely behind that tariff barrier, they have one factor of the most important character which we have not, and that is enterprise—not on the part of the engineer-organizer, but on the part of the financier, and this greater capital enterprise may be doubtless accounted for by the greater protection for capital which the tariff wall provides. American manufacturers of motorcars did not begin producing in the quantities they are now doing all at once. There was a time when they were producing no more than we are to-day, and if we take the Ford car as an illustration, as probably the highest development of American producing methods to-day, it may be pointed out that the first manufacturing programme laid out for the production of that car was not for the 300,000 turned out to-day, but for 10,000 vehicles only. At that time, however, probably, no manufacturer, either in America or here, produced more than a tenth of that number of any one model, and the Ford programme could then have been carried out just as well in England as in America, for at that time even farseeing American producers thought Ford was mad in laying out to produce such a large number of a single type. Yet, considering the prices ruling for cars in those days, in the States as well as here, had the same scheme been adopted in this country, the American markets, as well as those of Europe, would have been at the mercy of the producer who had done so—despite the tariff wall—until such time, of course, as the American producers tumbled to what was up and adopted the same methods. But here was the point. Ford was able to find capitalists to back him in his enterprise of producing 10,000 cars before he had sold them, whilst the attitude of British capital was at that time—and still is to a large extent—exemplified pretty much by the remark made to me twelve or fourteen years ago by the then Mayor of Coventry: "Motors! Motors!" said he. "Would you ever sell any if you built them?"

Depend upon it that, given the opportunity and the capital, the British producer, not only of motorcars, but of anything else, is fully the equal of his American competitor. But to reduce the cost of labor on hundreds of individual pieces, means a very high initial expenditure, and this is the reason why so many of the lesser American makers to-day manufacture little in their own works, their cars being very largely "assembly propositions." It comes, in short, to a system of co-operative working; for whereas car manufacturers here, for the most part, pride themselves on making their own engines, let us say, and make them, of course, in the same quantities as their cars are produced, and as the British manufacturers of "trade" engines produce only in approximately similar quantities—in America, by reason of having the work of engine manufacture to do for a dozen different car makers an individual firm of engine builders is enabled to pay itself out to produce, say 50,000 or 60,000 engines to one pattern, and can, consequently, adopt all those methods of special tool arrangements which go to reduce cost, and, as a result, can actually supply the different firms using their engines at prices less than they could produce the engines for themselves in their own works, in the quantities in which they could use them.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Automobile Lamps Ignite an Oil Pool.—Two young women were burned beyond recognition, at Oilton, Okla., when the lamps of the car in which they were riding ignited with a pool of oil and gas that had collected in a draw on one of the oil leases. The driver saved his life by tearing off his clothing but was unable to assist his companions.

No Signal Lights Displayed.—A man was killed near Maywood, Mo., by running into a ditch at the bottom of which was three or four feet of water. It appears that an excavating machine had been at work in the roadway and that no light or other signal had been left to warn travelers of the hole. Other occupants of the car escaped but one man was pinned beneath the car and drowned.

Attempted to Make Road Record.—A man was instantly killed and the driver suffered concussion of the brain when driving at the rate of fifty miles an hour near Sugar Grove, Ill. The car plunged into the railing on the bridge at Edwards River. The great speed at which the car approached was occasioned by the determination of the men to set a new road record.

Driving with Lights Out.—Two men and a woman were killed and another woman will probably die, as the result of an automobile accident between Helena and Butte, Mont. The driver of the car noticed that his lights were not working properly and asked the occupants of another machine in the lead to drive slowly so that in the event of trouble he could follow them. At the foot of a hill the lights on the rear car went out. When halfway up the machine skidded and went into the ditch, overturning and pinning the victims beneath.

Steering Gear Did Not Work.—Two persons were electrocuted and two so badly burned by electricity that they will probably die when the car in which they were riding in Cutler, Cal., crashed into an

Digitized by Google

electric power pole, breaking the pole and precipitating the heavy wires on the occupants of the car. It is said that the car was going at a slow rate of speed but the steering gear did not work. The pole was declared to be rotten as the impact was not heavy enough to injure the occupants and only damaged the car slightly.

Neglected to Throw Out Clutch.—Near Ambridge, Pa., a man was fatally injured, having received a broken neck and both legs were fractured. It appears that the man started to crank his car and neglected to throw out the clutch. It started forward suddenly knocking him down and injuring him as above stated.

Attempted to Avoid Mud.—Two young men were killed near Lette, Ia., when one of the young men in order to avoid a mud spot at the foot of a hill skirted the edge of the grade which is probably 30 feet high at that point. The machine skidded and left the road throwing the occupants into the ditch below. One of the young men's neck was broken and the other received a fractured jaw that must have caused instant death.

Dynamite in the Car.—Four persons were killed and twelve spectators and employes of plants nearby were injured at Syracuse, N. Y., when thirty pounds of dynamite exploded in an automobile. Two of the men that were killed had brought the dynamite near Onondaga Creek to recover the body of a drowned boy and in unloading it the dynamite exploded. An unidentified infant was killed and heads and limbs were torn from bodies and thrown forty feet from the wreck.

Collision at Crossing.—A mother and son were killed at a crossing near Dalworth, Tex., in a race to reach the bedside of some one who was critically ill. It is believed that the driver thought the eastbound express car which he saw approaching would stop at the station but it did not. The car struck the automobile full force and the occupants of the car were hurled into the air. The mother and son were killed instantly and the driver was severely injured.

Wheel Came Off.—One young lady has a fractured skull and another received a broken arm in an automobile accident at Laporte, Ind. According to reports one of the young ladies was driving and was going at the rate of 25 or 30 miles an hour when the wheel either collapsed or came off.

A Mile a Minute.—Two women may die at Oklahoma City, Okla., as the result of injuries received in an accident when the driver going at high speed crashed into a curbing. Two other women of the party were slightly hurt. It is stated that the driver was going a mile a minute and was returning from a club house where they had been drinking beer.

Too Near the Edge of the Road.—One man was killed, another may lose his eyesight and two others were injured at Livingston, Ill., when the driver drove too close to the ten-foot ditch which parallels the road at that point. The car overturned, pinning one man beneath and breaking his neck. The others were injured as above stated.

An Optical Illusion.—A man was killed at Somerville, Mass., when driving a car in the early morning haze, he started to turn down a street which appeared to be open at the farther end. When he reached the end of the street he realized he had entered a blind way. He was going at high speed and in an effort to avoid a collision with the building which closed the street, he turned a sharp angle and caused the car to turn on its side. The man was thrown out and received a fractured skull. He was dead when picked up.

Failed to Heed Signal.—At Maquon, Ill., a man was badly injured when the car which he was driving turned over in the ditch, pinning him beneath. It is stated that he signaled with his horn for the driver of a buggy to turn out for him to pass, but the man ahead failed to give the road and he was forced to either hit the rig or go into the ditch. He chose the latter and was thereby injured as above stated.

Attempted to Make Turn at High Speed.—Three women were injured at Denver, Colo., when the driver of the car attempted to make a turn while going at a high rate of speed. The driver lost control of the car which skidded and smashed into a telephone pole. Two of the women were badly cut and one received a broken collarbone. They were taken to the hospital for treatment.

Blowout Causes Accident.—One young man was killed near Hinsdale, Ill., when the automobile in which he was riding with three companions rolled over on a dangerous bend in the road. There is a high bank at this point and in order to make the turn cars usually take the curve on the outside. As the driver turned the wheel a rear tire suddenly blew out. The car skidded from the road and rolled over. The other occupants were thrown free from the wreck but the driver held to the seat and was found in a dying condition.

Killed on First Trip.—Losing control of his car which he had just purchased and was driving home, a man was killed near Bad Axe, Mich., when the machine left the road at a curve and plunged into a fence. He landed on his head and his neck was broken.

Steering Wheel Broke.—A man was killed at Charlottesvile, Ind., when the steering wheel broke and the driver lost control of the car. He received a fractured skull and died soon after he was taken to the hospital. The other occupants of the car escaped injury, with the exception of the driver whose face was badly lacerated.

At a Turn in the Road.—At East Northport, Long Island, N. Y., two cars, both traveling at a high rate of speed and in opposite directions, reached a turn in the road at the same time and collided head-on. It is stated that it is impossible to see far around the curve at that point. The lighter car rebounded across the road and turned turtle, crushing a woman beneath and throwing the other occupant out. The driver of the other car lost control of the machine and it turned turtle in the ditch. One woman was killed and three people severely injured.

Smoking While Driving.—Two men were injured at Rochester, N. Y., one having severed an artery in his right wrist and the other being rendered unconscious, when a touring car in which they were riding crashed into a telegraph pole. It appears that the driver was smoking and sparks from his pipe ignited with his trousers and in trying to extinguish the blaze he released his hold on the steering wheel, and the car darted into the direction of the telegraph pole.

AUTOMOBILE SCHOOLS.

The Kind of Instruction Received in the Y. M. C. A. Course of Lessons.

From Felix J. Koch, Ohio.—In one of the big mid-Western cities, one of the great charitable movements devoted to keeping the youth of the land off the streets, plastered billboards, walls and fences with the slogan: "We want your boy!" Some mysterious wag chalked beneath the query: "What for?" To-day in innumerable cities the United States over the Young Men's Christian Associations are answering this query by replying, in so many words, that they are taking boys and men and teaching them either how to save time and money through conquering waste and breakage on their own automobiles, or to earn a clean, decent livelihood as chauffeurs. Or still again to become repairmen and earn a good living that way. In fact no one phase of educational work for a long time seems to have taken the grip of the Y. M. C. A. auto schools.

Suppose J. Perceval Roosa, for illustration, wishes to enter the Y. M. C. A. auto school. Possibly old man Roosa has yielded to his son's importunities and is to buy a new car on condition that "Jack," as they call him, will attend to it. Perhaps young Roosa has a car of his own and doesn't half relish having to leave it at the repair shop every time there is some mishap. Or, as already suggested, more likely than not Roosa wants to learn the trade of auto-repairman, or turn chauffeur. Whereupon he hies himself to the nearest Y. M. C. A. headquarters that has an auto school attachment.

In most of such schools it is not stipulated that one need join the Y. M. C. A. in order to attend. In one instance the fee charged is $52, and this paid the applicant may choose between a day course, covering five weeks or a night course of ten. Obviously, more take the latter course, leaving the daytime for their regular work. Lessons run from seven o'clock until nine-thirty. New classes start each month and will average say fifteen men to a class. The students are almost all of them young men. Students are taken from the age of sixteen years up.

The first lesson is given, as a rule, in the tire department, students passing in turn from department to department of the school. Starting with the commoner tires, they learn all about them and then how to repair them. This work takes three or four lessons, each point being made so clear that the veriest tyro must know all about it.

Without doubt, one teacher tells me, the automobile tire gives as much, if not more, trouble than any other part. Therefore the construction of pneumatic tires is taken up in detail. Also treads, rims, attaching and detaching, care and repair of the inner tubes and casings. Students do the actual work of keeping the tires in repair on the several automobiles that are used for road practice and also the other machines that are brought into the school work-shop. By this method the student does the actual work and therefore becomes proficient. There is also given a thorough drill on how to save tire bills. The owner of a car appreciates any saving that the chauffeur may be able to make along this line and this fact is made impressive.

The student then graduates to the rear axle. There he is taught by varied examples, the full floating, the three-quarter and the half floating axles. Most cars the men will use have full-floating axles so that most time is given to this. The actual work of dissecting rear systems, says our informant, we find to be the most helpful, as it gives the students a clear insight into the working and adjustment of all the standard systems. Class room lectures are given on transmission and steering-devices, which gives the student the working principle of each system. Brake systems are taken up in detail and the working parts carefully explained to each student. These details are learned in practical shop work. Each student is given opportunity to see the different makes of the school's own cars; also those that are used for repair work.

Having become thoroughly grounded in this, the future motorist continues on a study of the carburetor and engine work, engaging in this for about two weeks. Bright fellows can learn to understand the various carburetors and their adjustment quickly, but there are other phases to be taught beside. The student then passes to a machine equipped with modern lathes, electro-grinders and drills, and all the necessary shop equipment to make it practical for the repairing and up-fitting of cars. In this shop he receives practical instruction in lathe and machine tool work.

The road cars of the school are kept in first-class condition by being overhauled by the students whenever they are in need of repairs. This is done under the supervision of expert instructors. Such practical shop work is of sufficient breadth to enable students to do similar work if they contemplate running a repair shop. A good many students start garages and they always find this part of the course very beneficial.

Then follows the ignition, three weeks to a month of it practically completing the course. The ignition system of an automobile offers greater opportunity for trouble than most any other part of the car, and in order to overcome this, one of the best instructors is in charge and each student is given a thorough, practical drilling upon the different systems.

The course considers batteries and amperage and wiring in series and multiple, together with their construction and proper voltage; magnetos, low and high tension currents, induction coils, vibrations and master vibrators; also single and multiple coils. Then switches of different kinds are taken up as well as timers or commutators and their principles and construction. Spark plugs are also studied until they are fully understood. After the lectures the students are set to work on various parts of the car.

One evening a week, as a rule, is given to a lecture on a specific subject. The next week there are demonstrations and practical work. Breakage is not charged against the student.

Completing this work the students pass to the motor itself where the different styles are taken down and reassembled. An instructor gives his personal attention to each student. After the motors are set up, they are expected to run perfectly, and if they do not, the students themselves are asked to locate the trouble and adjust it. Practical work is given in the grinding of valves, taking up bearings, carbon removing, oiling and adjusting every moving part. This department is given special at-

Digitized by Google

tention, as much depends on the thorough understanding of the motor. Motors are provided to give students a thorough understanding of the standard makes employed. The engine used more than any other type is the four cylinder.

By about this time the student is ready for practical experience on the road. If you have a night you think you can spare from a given subject, you take a driving lesson. Or, if you wish, you wait until completing the course. This done, you take the examination. Here there is reviewed everything you have learned. Ninety-eight questions were asked one candidate in a quizz of the sort not long since. Passing successfully, one received a diploma and if desired has his name entered at the several Y. M. C. A. employment bureaus. Then some fine day Jack Roosa receives a call to apply to so-and-so for a position. He goes, the employer looks him over and tries him out. He does splendidly and is taken on. The first lap is thus conquered in the long race to a great garage and endless machines some day, all his own.

BRITISH AUTOMOBILES.

Manufacturers There Acknowledge Benefits of Tariff to This Country.

Henry Sturmley in Motor of London.—A few weeks ago I pointed out how large output enables American firms, by the use of highly-specialized machinery, to overcome their handicap of high wages, and to beat the European manufacturer on price every time, and I further showed how the high wages they had to pay in the States is, in itself, a factor which, by encouraging this specialization and enabling it to be commercially economical on a smaller quantity production than would be the case in Europe, actually helps the American producer towards this end. I now see that a Colonial reader rather takes me to task for defending the British manufacturer on the ground I did, and urges that, had the British manufacturer specialized and laid himself out to produce in quantity at quantity price, he would by now have had the quantity sales which are, of course, necessary to keep such an organization going. In this I fear my critic is wrong, and his criticism shows that he has not fully grasped all the factors in the situation.

Considered without reference to other considerations which affect the question, there is ground for his contention. All other things being equal, the lower the price of an article the larger will be the sale. That goes without saying. But, unfortunately for the British manufacturer, all other things in this case are not equal by any manner of means. My correspondent has forgotten that there are such things as tariffs, and that by far the largest and most receptive market in the world has, until quite recently, been closed to us by a tariff approximating 45 per cent., in addition to the natural handicap of boxing and freight charges, and that even now, although things are better, this tariff wall is still over 20 per cent. on motor goods, which is quite as formidable an obstacle as under the old rate when the local conditions which exist to-day behind that tariff wall are taken into consideration—conditions which themselves are the result of the protection provided by the barrier.

Had there been no tariff barrier between the two countries, British manufacturers would have been upon safe ground in laying out for quantity production, as their market would not have been restricted; but, as it was, five or six years ago, when specialization first took hold of the American motor trade, the entire motor trade of Europe and the rest of the world, bar the United States, was but a very small proportion of what it is at the present time—barring war conditions, of course—whilst the market in the States was already as large, or larger than that of the rest of the world combined, and the American producer was absolutely protected in that market. Moreover, he knew that the factor of price rules the purchaser in America very much more fully than is the case here, and he had the very fullest encouragement to go all out for standardization, concentration of effort and a price campaign, with a result with which we are all of us now familiar.

It must further be remembered that, when this campaign commenced in the United States, conditions were different here from what they are now. Very few firms indeed in this country were making any profits worth talking about in the motor trade, and public opinion in regard to cars was so varied that it would have been difficult to select any one model to work upon. I remember, about that time, interviewing a number of capitalists in regard to the manufacture of a car of considerable simplicity and moderate price, but the opinions I met with were absolutely contradictory. Those who were not motorists seemed to think nothing would be worth tackling except a very much cheaper car than was under contemplation—the £100 car, in short, which at that time was not a possibility—whilst those who were motorists would not look at anything so unpretentious as that which I had in hand, and the only sort of car they felt there was any future for was a 60 h.p. vehicle, which should be better—i.e., faster—than anybody else's. Had we had the markets of the world, and especially the markets of America open to us, as well as our own, very possibly British capitalists would have plucked up sufficient courage to back a 10,000 car proposition, which, it will be remembered, Ford's was in the first place; but, whilst they were waiting to see somebody else make money out of motoring first, American capitalists, taking their courage in both hands, stepped in, and backed their manufacturers, and as a result their smile to-day is of the order that "won't come off." It is still possible, in one or two branches of automobile work, for British manufacturers, if backed by ample capital, to tackle manufacture on the basis of a "price proposition," and in doing so—now that the American tariff has been reduced—to operate for sales in the markets of the world, America included. But these openings are being rapidly closed up by American enterprise, and they do not exist to-day in the direction of the low-powered or moderate-powered touring car, which has been brought to such a figure in the States that even the reduced tariff wall is a full and efficient bar to our entering there. Given free trade throughout the world the British manufacturer would whip the world, but, under existing conditions, he cannot help himself. An adequate protective tariff throughout the Empire would help him to secure and retain the trade of the Empire, and that half-loaf would be better than no bread. Without it, in all competition where price is the ruling factor in securing

Digitized by Google

business, he is handicapped out of it, and, as I have so often said before, he must depend upon the high quality of his goods for his market—and a high quality market is not a quantity market.

MOTOR TRUCKS.

A Body Design for a Four Ton Coal or Other Load.

The motor truck is becoming more useful every day in New York, as well as other large cities, as it really is a necessity in mostly every line of business, where heavy loads are carried, for instance, coal, stone, iron, pipe, etc.

The illustrations show a design of a four ton coal body mounted on a Peerless chassis, and is so constructed as to save time in making deliveries in this line of business. With a careful study of Fig. 1 it can be clearly understood what great advantage this design of body has over the designs of the past. First, the driver need not turn a crank to raise the body to the angle required to unload its contents. He has only to release the pin A from C which holds the coal chute B in place on the chassis. He then connects the chute with the outlet D, raises the sliding door E, and the coal is thus easily discharged in the coal hole or cellar. This body has two compartments, F and G, divided by a panel H, each containing two tons of coal. The same method is required to operate the second compartment when the driver arrives at his next destination. This body is made of sheet iron with supports I, and the floorings as indicated by dotted lines J, are of an angle of 20 degrees and 38 degrees. The sides are 80 degrees, therefore giving the proper angles to permit the coal to travel at the desired speed.

One important feature of this design of body is that it stands lengthwise with the curb, and does not interfere with traffic. It is also quickly unloaded, and the tonnage is equal to that formerly handled by four two-horse teams at less than one-half the cost of carriage. Fig. 2 shows the angle of the outlet from the floor of the body, and the 80 degree angle of the sides.

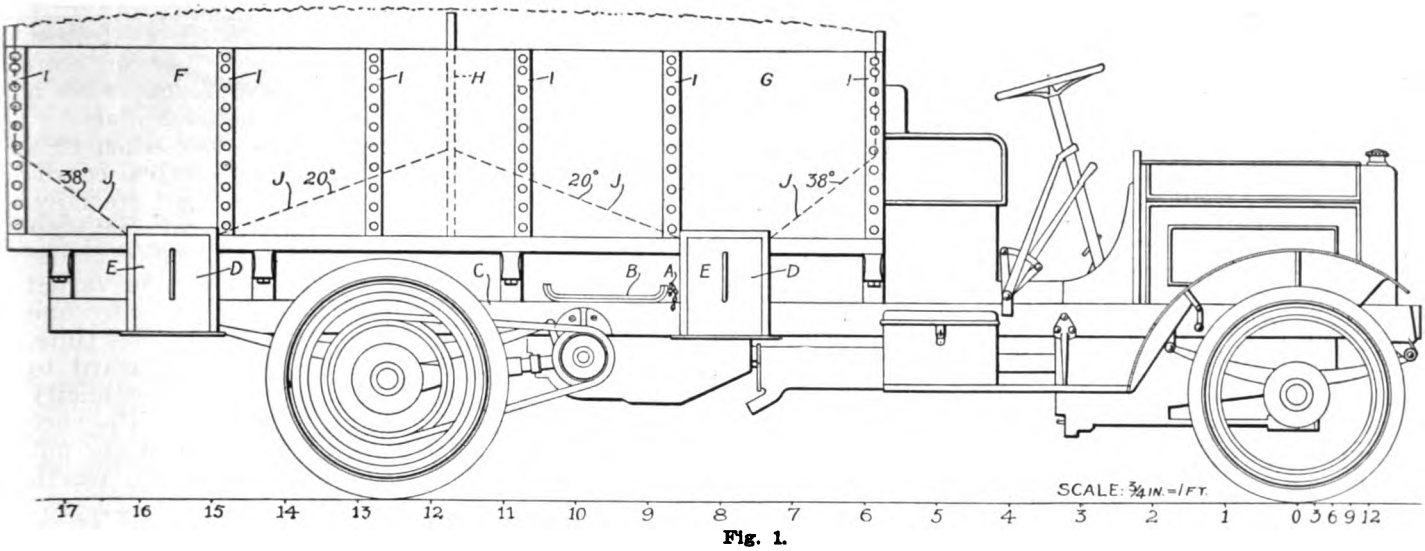

Fig. 1.

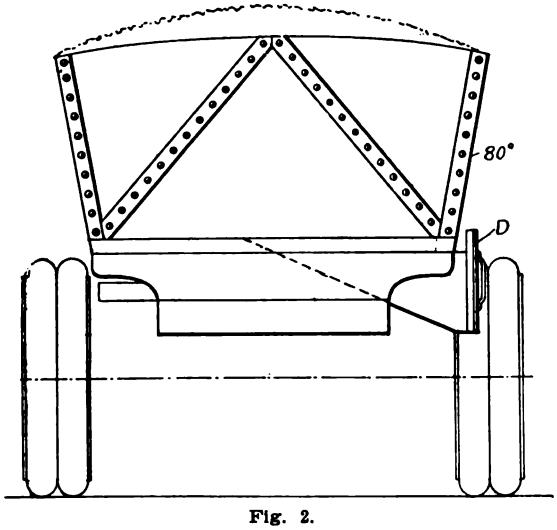

Fig. 2.

Evidence of Under-Inflation.

When new tires fail early in life and have to be sent back, either under guarantee or to be retreaded, the maker frequently puts the blame upon the user and accuses him of under-inflation. The user generally believes that the tire maker is bluffing him, and endeavoring to get out of his guarantee. He does not realize that the tire maker can tell for an absolute certainty whether a tire has been run under-inflated or not. There is no reason why the user himself should not be able to tell on inspection of his covers whether his tires have been under-inflated. It is simply a matter of feeling the cover when taken off. A new cover, or a cover which has been properly inflated and of a correct size, will always have a feeling of liveliness about the walls when it is bent or worked with the fingers. The first thing which under-inflation does to a tire is to cause the layers of the canvas in the fabric to separate or lose their adhesion to each other to a certain extent, with the result that they become "dead" and have a feeling which is quite different from that of a new cover.

Home vulcanizing is quite a nice hobby for the careful motorist to cultivate and it saves money.

An Important Court Decision.

A new and interesting ruling has just been made in the Court of Common Pleas of Cuyahoga County, Ohio, as to the liability of a garage owner because of injury to persons while being driven in their own cars by a driver furnished such persons for hire by the garage owner.

The case was that of Jones against The Baker Motor Vehicle Company, and it appeared from the evidence that Mrs. Jones was the owner of a car which was kept by the Baker Company in its garage as a "boarder" and that upon her call the Baker Company would furnish her a driver at a fixed charge per hour, and that these drivers were instructed by the Baker Company to drive "as directed by the owner" while out with the car. It appeared further that while an employe of the Baker Company was driving Mrs. Jones one evening, about dark, and through a drizzling rain, the car ran into a dirt wagon standing by the roadside, without any lantern on it. Mrs. Jones, who had been riding backward, in the front seat of the machine, claimed to have been injured as the result of this collision. The court charged the jury that, as a matter of law, the driver of the car was, at the time of the accident, the agent and servant of the Baker Company and that if the company had not exercised due care in selecting a careful driver, or if the driver was negligent and his negligence caused the accident, the company was liable. This ruling of the court is probably the first of its particular kind and if sustained by the higher courts means, as a practical matter, that a garage owner or other person who supplies drivers to the owners of cars, in the manner above described, is absolutely liable not only to the owner of the car but to third parties as well who may be injured through the carelessness of the driver.

Tire Repair.

From C. H. Kenyon, Connecticut.—I wish to give those interested an idea of what may be done with

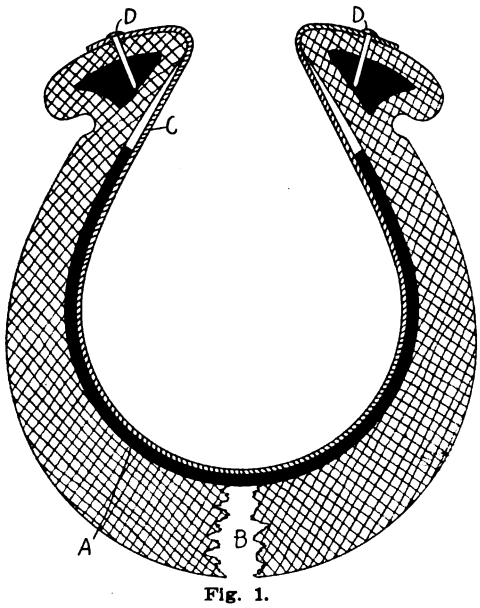

Fig. 1.

an old tire shoe, as shown in the picture. This tire was run over 1,000 miles after my patch began to touch the road. You can count the layers of fabric as seen in the snapshot and the tire is still in use. Now this is my secret—if it is one: This first layer, A, Fig. 1, is composed of an old inner tube split open and long enough to extend 5 or 6 inches each side of the blowout. Next is a piece of the heavy sail canvas or other strong fabric. Then fasten it with the aid of a few small carpet tacks, put in about 2 inches apart, to hold the fabric from being forced through the blowout hole. You will then get the

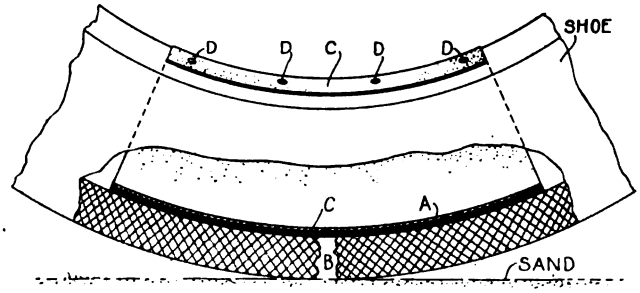

Fig. 2.

results as shown in Fig. 2. It is hoped that the drawings will indicate what may be done and the result.

Temporary Tire Repair.

The writer once found himself stranded over a hundred miles from home with the spare tire burst. No gaiter or special patch was at hand, and the expedient of folding a piece of rag four times and then placing it between the tube and the weak part of the cover was tried, merely to enable the next town to be reached. It held so well that the car was run the whole way home, but a subsequent examination of the tire and its contents showed that the repair would not have held up very much longer. Naturally, no high speeds were indulged in on the way home.

License Plate Colors.

In the March number it was stated that the license number plate for the State of New York was colored red on white. This was incorrect. This year it is black on yellow.

Due to the War.

The Paris correspondent of the New York Evening Post says that English and French army orders already placed in the United States for automobile trucks amount to upward of $30,000,000.

Protected Wiring.

The wiring of a motor car requires the best possible protection. As a rule the wires should be well insulated and be carried in copper tubes that are impervious to oil and water.

Clutch Action.

The "take-hold" of a multiple disc clutch depends largely upon the relative speed of the two surfaces. Where the difference in speed is great there is poor action and great wear. Thin oils favor quick seizure and heavy oils make action slower.

When the steering column wabbles you must not expect to get quick response to your efforts to guide the car. Some manufacturers brace the steering column to the cowl to make it firm.

MOTOR TRUCKS.

Their Cost, Care, Maintenance, and How to Get the Most from Them.

By J. L. Black of the Motor Truck Club of New Jersey.—There has been entrusted to a committee, of which I have the honor to have been appointed chairman, the preparation of a paper upon the care and maintenance of motor trucks. These are matters of great interest and importance to all users of motor trucks, and as one having the direct care and upkeep of a fairly large fleet of various makes, I can say that while there are some few fixed rules which must be followed to secure even the semblance of results, there are individual problems to be overcome in the case of each one of us. It is probable that in the main our problems are much the same; it is also likely that that which becomes one man's big trouble is of lesser moment than something else to his neighbor. We will therefore endeavor to look at the question in the light of our own experiences. While this paper hardly begins to cover all the points we might gather under the headings of care and maintenance, still if it will start questions and action in the proper direction, the committee will feel that some good has been accomplished. We therefore cordially invite your criticism and questions.

Lubrication, possibly, is the most important point; certainly it applies to all, although some owners have been particularly fortunate in having secured a man to drive or take care of the truck who was first trustworthy, and secondly competent. Trustworthy first, because upon being instructed he could be depended upon to perform his duty thereafter. There can be no valid excuse made where any motor truck fails to perform its work through lack of proper lubrication of all its parts. There are few if any trucks now built, which, when adapted to the work and properly cared for, will not be highly efficient in results.

All motor truck builders now place particular stress upon, and direct owners' and drivers' attention to, the proper lubrication of trucks—in fact, some have very elaborate charts illustrating points to be taken care of and how. Of course, in the case of those who have purchased these particular trucks, little need be said, as these instructions are based on the experience of those who know them intimately. I might call your attention, however, to the necessity of a regular changing of the oil in the crank case of your motors. This is because all oils in use in internal combustion motors lose considerable of their lubrication qualities, and also in time become impregnated with minute particles of metal and dirt; they also become carbonized to a greater or less extent. The mere addition of fresh oil continuously will not answer; this practice but puts off the day of reckoning.

While in most instances trucks receive more or less intelligent and careful lubrication of motors because drivers quickly learn that no oil, no work from motor, it is to be regretted that such is not the case with the balance of chassis. This is due to several causes, the first and principal one being negligence; the second, ignorance; the third, indifference; the fourth, which we fear is more prevalent than is commonly known, is lack of sufficient time daily being allowed the driver to properly do so.

Taking up the first reason: The indolent driver soon finds out that his truck will stand an enormous amount of abuse, and thereupon decides that the lubricating will do some other time—or something to that effect. This man, it is to be hoped, is soon found out and excused from further troubling. The second reason, ignorance, is a condition which of course will always be more or less with us, but can be more easily overcome than any other. Third, indifference: This, like the first, will soon show for itself in more ways than one, and can be overcome in various ways. The fourth, lack of time, is, we believe, a serious one. It involves a great many phases which we have not now the time to go into in detail. I would like to say, however, that careful and systematic lubrication of all chassis parts—some of which are unfortunately quite inaccessible—will well repay any truck operator or owner in the added dependability of his truck and the decreased cost of maintenance.

As an illustration of the truth of the above, I wish to show you some interesting figures taken from our own records. They are of three cars of a well known make which have done substantially the same work and mileage:

	No. 1	No. 2	No. 3
Gas	.0463	.0527	.0367
Oil	.00248	.00373	.00231
Repairs	.0293	.0315	.01384
Tires	.0538	.0532	.0523
	.13188	.14113	.10515

In the case of the driver of the No. 3, who is a very conscientious and methodical man, you will note his running expense per mile is consistently lower for all items. And it is of great importance to emphasize the fact that when his machine was taken down for a general overhaul, it required less than half the replacement of parts due to wear than was the case with either No. 1 or No. 2.

We might divide the maintenance question into two classes: Large fleet owners and the individual owner or those who have a single truck or up to perhaps half a dozen. In the case of the large fleet, there can be no doubt that same should be put into the hands of a competent man and cared for largely upon the owner's premises. The smaller installations cannot afford the overhead expense, as a rule, involved to do this, therefore must depend upon the drivers to a very great extent, and upon such service stations as the agent of their truck maintains. This works out very well in a great many cases, but in others the combination of indifferent drivers and poor service stations has probably produced more discouraged and disgusted owners than any other cause.

I believe that the spirit of our organization is to eliminate as far as possible these conditions—in the case of the driver, to instruct, and in the service matter to have a get-together feeling and help each other in our problems.

At present it is appropriate, I think, to mention the system now in use by me, and which I believe is followed in general by a number of others. It involves a careful inspection of the truck upon its return to the garage after each day's work; also a written and signed report of driver of any deviation from the normal condition of the car as noticed by him during the day, and immediate correction of faults, if any, on the principle that "a stitch in time saves nine." The car is also washed thoroughly at

Digitized by Google

least once a week. In addition to this, there is a thorough overhauling and painting after about 15,000 miles, this distance seeming to work out very well in a number of cases coming under my notice. I wish here to read you a clipping taken from one of the trade papers which bears upon this subject:

"Bought in 1904, seven in February and the rest the same year, a fleet of eighteen single-cylinder air-cooled Knox commercial vehicles owned and operated by the Motor Transportation Co., Chicago, Ill. Was the first to be used in the Windy City, and all are running to-day in their regular service to the complete satisfaction of their users.

"The Motor Transportation Co., as its name implies, is a concern whose business is the maintenance of motor trucks. Fifteen of the eighteen Knox trucks are used by Fuller & Fuller, wholesale druggists, one more is used by Clarence Hirschorn & Co., wholesale cigar dealers, and the other two are retained as spare vehicles by the owning comapny.

"The company states that it would not trade these veterans, old and dilapidated as they are, for as many spick-and-span 1915 models of any make. They are over ten years old, but the Motor Transportation Co. states that they are good for ten years more. The secret of durability, as this firm has learned, is constant care, not continual repairs. By taking a stitch in time, the proverbial nine saved makes the difference between high depreciation and continuous efficiency.

"The Fuller & Fuller trucks make from 40 to 60 miles a day, 6 days a week, those on suburban runs going out as far as 20 miles from the city.

"* * * * Each of these trucks, when it returns to the garage at night is given a thorough inspection, such work as is necessaary being done at night, and the bigger jobs on Sundays."

It is not amiss at this point to touch upon the matter of cost keeping or records. It is likely that a large proportion of those owning and operating motor trucks do not keep any sort of systematic records of the performance of their vehicles, as evidenced by observing the great many trucks on the road which are obviously not paying their owners because of their poor condition and also the manner in which they are being handled—or, I should say, perhaps—loaded and routed. It is probable that this matter will form the basis of some future paper in our club.

We are all of us interested, of course, in tires. I wonder how many of you, after purchasing your trucks and having worn out your first tire—usually far short of the guaranteed mileage—have had your tire man tell you that your tires would not give you mileage as they were not large enough to do so, even though they were sold to the manufacturer of your car originally to carry no more than you load upon your truck, and, after being convinced that he was right and putting on the next larger size, have found that at about the same mileage, or only slightly more, that it also was worn out. I might say this has been somewhat the experience I have been through.

I observed early some peculiar results, which have apparently attracted the attention of tire manufacturers recently, namely: In our service we had a number of different makes and styles of tires performing practically the same work and under the same conditions, the mileages, however, being at a great variance. One make was of a high, rounded section; others of flat, wide section. Our experience has been that we received always a very great many more miles for the high, rounded tire than we received for the others. Also, I noted that our maintenance expense upon such parts of truck as were subject to road vibration was very much less in case of the high, rounded tire. The above does not seem to have depended so much on the make of the tire as on the form. In the past few months we have had occasion to change the flat form as made by one company to the rounded high type manufactured by the same concern, and have been able to secure the same results as before mentioned.

In connection with the tires, I should like to call your attention to the figures before mentioned, as showing the results of careful handling of cars on the road, illustrating the advantage of having the proper man on the truck.

In conclusion, the matter of proper housing or garaging of trucks is one which is of no little concern to many owners. There can be no doubt that it deserves the careful consideration of all. The garage should, if possible, be light and provided with means of heating in Winter, these points tending to induce the driver to take better care of the machine; also in Winter a car kept in a warmed garage is much easier to start. The garage or place where the car is stored should in all cases be provided with means for washing car. It is surprising how many bolts, nuts, etc., requiring attention show up after an accumulation of dirt has been removed; besides it certainly does not detract from the appearance of the truck.

I believe that most of us realize that our trucks, aside from their utility, are one of the best advertisements we have.

A BIG SPARK.

Why an English Expert Claims Its Advantage Is a Fallacy.

From "Veritas," London.—There are some fallacies, relative to motoring topics, that are very hard to kill; perhaps it is that they always elude the knock-out blow. The season of the year may also have something to do with it, as the writer has observed that they mostly "bloom in the spring"—to quote the words of a well-known comic opera. Be this as it may, our old friend, the "Big Spark" fallacy, has just appeared above ground, and its claims are being carefully considered by an interested group of fallacy enthusiasts, armed with magnifying glasses of the "why not" type. Thus, they contend, if the size of spark now used, viz., one that jumps a 1-50 in. gap under compression, be increased so that it can jump ¼ in., this should solve starting problems and give a more rapid ignition, quicker combustion and more power—why not?

The enthusiasts further ask whether it would be beyond the range of electrical science to intensify the magneto spark. A vast amount of scientific research has actually been done on this "big," or, as some prefer to call it, "fat" spark theory, and it has been conclusively shown that increasing the amount of energy in the spark beyond a certain well-defined limit does not effect anything; hence it is that the present-day standard spark is found to fulfil all requirements. True a large engine will have or should have, a more powerful magneto than

Digitized by Google

a small engine, though a small magneto would run it; but it would probably be difficult to start up on it. The large engine is so much more difficult to swing, and thus the small magneto would not have a chance of generating a strong enough initial spark.

If there ever had been anything in the "big" spark theory, low tension magneto would never have been discarded despite the mechanical defects of the make-and-break sparking plug necessary with that system. These would undoubtedly have been remedied if the spark itself had any particular virtue compared with the present-day high-tension or "jump" spark. The low-tension magneto spark has all the characteristics that the "big" spark enthusiasts require, such as great heat, volume and density. The maximum break is something between ⅛ in. and ¼ in., according to the size of the magneto. There is no doubt whatever that when in normally good order the old low-tension system was a very good starter, because the break of the circuit was practically constant at any speed, and this always ensured a voluminous spark.

Provided that the spark can jump the gap of the plug instantly under the full compression, it will start the ignition of the mixture. It is nevertheless often overlooked that the function of the spark is only to start the combustion. The propagation and completion of the combustion depend on factors entirely different in characteristics from the spark. Thus, there is the strength of the mixture, the degree of compression and consequent heating of the mixture (the hotter the mixture the more quickly it ignites); then of great importance is the state of turbulence of the charge. For several good, practical reasons the charge cannot be fired at the theoretically best position, viz., in the center, and thus spread the ignition uniformly through the mass, but it is ignited at the edge, and the flame has to travel from the edge right through the mass. This disadvantage can, to a large extent, be remedied by making use of more spark energy in the correct way, i. e., not as one big spark, but as two or more sparks occurring at different positions and perfectly synchronized or timed. Unless perfection in this factor is obtained, the extra sparks are wasted, because the combustion of the gas has already been accomplished by one of the sparks, but at a slower rate than would have occurred with several sparks.

It may be asked why, if two or more ignitions are an undoubted advantage from the point of view of an increase of power and ease of starting, the principle is not generally adopted? The answer is simply that it complicates the ignition system, and, furthermore, the engine must be designed to take the extra sparking plugs, and, therefore, the advantage can only be obtained at an unwarranted extra cost. It may, in some few instances, be found that double ignition can be improvised by fitting an extra "series" type of plug over the inlet valve—not over the exhaust valve—but the instances where real advantage is obtained by such improvisation can at best be very few.

Light cars will have more chassis and body vibration than heavy ones. Soft shock absorbers are therefore more important for light cars than heavy ones. Rattling loose of bolts is more frequent in light cars than in heavy ones. Greater precaution against this is needed in light cars than in heavy ones.

Hot Weather Hints.

From the Chalmers Clubman.—For comfort on long tours, leave the top up. If you would cut down tire expense, watch the inflation. Keep the pressure at the number of pounds indicated on each tire.

Inspect the amount of water in the radiator daily. Keep it filled within an inch and one-half of the bottom of the filler neck.

Lubrication reduces wear. See that all working parts are supplied with an abundance of high grade oil and greases. Hot weather shortens the life of lubricants, hence frequent attention is necessary. Use medium oil in the motor.

Watch the spring clips. They must be kept tight. A spring cannot break in the center if the clips are kept tight.

Remember that you use your car more in the summer than in the winter and all adjustments should have correspondingly more attention. The use of a wrench in time saves repair bills.

Evaporation is more rapid in summer, hence distilled water should be put in the battery at least once a week, in accordance with instructions.

Always keep tools and a jack in your car. If you do not need them yourself, you may have occasion to loan them to some friend who has forgotten his.

Think of the man behind you when driving along a dusty road. Courtesy is not misplaced in a driving code.

When meeting another car at night, dim your headlights first. The other man will follow suit. This precaution may avert a serious accident.

Do not touch any adjustments or tamper with any parts until you know exactly what caused the trouble. Otherwise you may get everything out of adjustment. When in doubt, don't do anything. Sit down and analyze the problem.

Motor Truck Hauls 375 Sheep.

One truck hauled a flock of 375 sheep five miles into Charlotte, Mich., recently. The sheep were driven into crates on the truck and on six trailers. As the sheep weighed 15 tons and each wagon 1,500 pounds, the entire weight of the haul was over 20 tons. Several hills along the road were negotiated without difficulty.

Care of Springs.

Few people realize how much improvement in riding quality may be secured by lubricating the friction surfaces of the spring leaves. At least once each season the leaves should be taken apart and polished, and lubricated with graphite grease.

Retard Your Spark.

Even though you are sure that you can start your motor with the spark advanced without breaking your arm, it is not proper to do so. The thrust backward of an advanced explosion has a tendency to injure the motor.

Balky Starter.

When the starting motor stalls easily, and fails to spin the crankshaft as it should, you may be sure that either the liquid in your storage battery does not test up to 1275, or else the contact points of the line switch are not making good contact.

AUTOMOBILE VARNISHING.

It Brings a Good Profit When Done Properly and if Not Rushed.

From the Carriage Monthly.—Probably no class of automobile work brings a better profit than the touch-up and varnish job. There shouldn't be much unhanging; very little, in fact, beyond slipping off the wheels. Some painters do not even go to that trouble, although, for our part, we could never see any good excuse for squirming and twisting about these parts with a paint or varnish brush.

With the car jacked up sufficiently to let the wheels roll clear of the floor we are ready to begin work, which we do by removing all the loose interior furnishings, side curtains, mats, carpets, etc. Detachable lamps and a few other small fixtures may, of course, come off. Before rubbing the varnish proceed to match up a sufficient quantity of color, or colors, with that on the car. A better match can be made with the original color under gloss effect than with this same color under a dull effect. In mixing don't forget that sufficient varnish to make the color stand forth with some luster is advisable. In drying it then undergoes no change.

Rub the old finish simply enough to lay down the shimmer, and brush away whatever nibs and bits of dirt may lay embedded in the varnish. Perform a similar service for the chassis, only instead of using pumice stone flour and water rub with a handful of curled hair obtained from the trim shop. Before going over the chassis, however, these parts should be cleaned of all grease, oil, dirt and whatever other accumulations may be found. Not a pleasant job, and about the biggest one connected with this class of work.

Ordinary crude oil, one part, and turpentine, two parts, make a good softening up medium. Put the mixture on as soon as the car arrives. This will help to start the hard, adhesive grease and grit, so that by using scraping knives and wiping off often with coarse rags or burlap the work will be completed in due time.

Following the light rub all over, wash the car with clean water and dry off with the wash leather. Make use of a good wash or tooling brush to get sediment, pumice stone particles, etc., from molding crevices, doors and other parts beyond the effective reach of sponge or chamois skin.

Next proceed with the touching up. Touch only the spots in real need of color. Confine the color to the precise lines of the mar or bruise, use it sparingly, and avoid rough, thick edges. Over touching, in case the color is not a perfect match, makes a bad mess, and one impossible to remedy except by coloring the car over entirely.

After touching up, take the top in hand and apply to it any needed processes. If any dressing or renovating medium is applied use it sparingly. The good leather top will scarcely require more than a clean sponging off with tepid water with a few parings of castile soap beaten into it. Bows and joints need inspection and finishing if worn and shabby. Perhaps the lamps will need a coat of varnish-color to fetch them up to the standard of the other parts. Paint the radiator a thin coat of asphaltum or brush it over with some one of the bronze mediums. Now give the car a final wash-up with clean water and a kit of tools specially kept for this work.

This work means, in large part, success or failure for the finisher. The work cannot possibly be done too thoroughly. An hour of extra work devoted to washing and cleaning the car may mean $100 worth of advertising by a supremely satisfied customer.

First finish the upper panels, then the lower ones, then the bonnet or hood, next the chassis, which includes the fenders, etc.

During a rush of work, when demands prevail for immediate delivery, a medium hard-drying varnish capable of resisting, without spotting, the action of road accumulations is to be preferred. On the whole, it means more satisfaction to all concerned.

PRESSED STEEL WHEELS.

How They Compare With Wood or Wire for Pleasure Cars.

By O. A. Parker, Hydraulic Pressed Steel Co., Cleveland.—The idea of making an automobile wheel out of pressed steel is not new. More than ten years ago such wheels were manufactured and thousands of them were used as equipment on cars of American make. These wheels were assembled with the hub and the rim, in the same manner as an ordinary wooden wheel, each part of the wood wheel having been duplicated in the form of hollow metal, and the whole held together by riveting and brazing.

Recently the pressed steel wheel has come into considerable use abroad. Steel wheels are to be found on 26 per cent. of the models of cars on the British market, wire having 25¼ per cent. and wood 48½ per cent. In England there are being manufactured at least three well-known types of pressed steel wheel. In the first type the complete wheel is formed in halves, rim, felloe and spokes being formed together and the halves joined at the median line by oxy-acetylene welding. To form each half of the rim, felloe and spokes in one piece in this fashion requires a large number of dies. The steel is annealed many times, and in addition to dies, rolls are required to aid in forming the rim. There is about 36 linear feet of hand-welding in each wheel. With the second type of wheel ordinary tire-carrying rims are used, the felloe and spokes being formed in halves, gas welded at the middle line, and the rim secured to the wheel by means of two circumferential welds, one on either side where the hollow felloe joins the rim. This wheel requires about 43 linear feet of hand-welding. The third type of wheel is assembled in very much the same fashion as the American wheel of early manufacture. Each spoke is made separately in halves and welded down each side. The spokes are then welded to the ordinary tire-carrying rim and placed under compression by means of an expanding mandrel in the center of the wheel, while two side-plates of pressed steel are applied. These side-plates are formed so as to cover each spoke half way around and form the web between spokes at the hub. The best-known wheel of German manufacture is made in halves, without any felloe and welded at the center line. A socket is welded to the end of each spoke and the ordinary tire-carrying rim shrunk or pressed on and attached to the sockets by means of welding or riveting.

Practically all of the pressed steel wheels manufactured abroad have the tire-carrying rim made integral with the wheel, and the wheel is, therefore, made demountable at the hub. This requires special hub fittings and also necessitates carrying spare wheels.

Digitized by Google

It is at once apparent that a pressed steel wheel can be made of almost any required degree of strength by simply varying the thickness of the steel from which the wheel is made. It has been the object to so design these wheels in all sizes that there would be a reasonable margin of strength over that of the average wood wheel of the same size. It is possible to do this and at the same time afford a considerable saving in weight.

During the last four months over sixty wheel tests—about equally divided between steel and wood—were made by the Case School of Applied Science, Cleveland, Ohio, under the personal direction of Professor R. H. Danforth. These tests resulted in such a large amount of data that only average results can be given here. The tests were chiefly of two kinds—rim pull, in which the wheel was mounted upon a rigid spindle and the load applied to the rim at one point in a direction parallel to the axis of the wheel, and center pull, in which the wheel was laid upon a rigid ring and the load applied axially at the hub. All of the steel wheels tested were selected at random from stock and all of the wood wheels were brand new.

36 x 4½ pressed steel wheels with internal clips, weighing, without hub or tire-carrying rim, on the average 21 pounds, were tested in comparison with three different types of 36 x 4½ wood wheels with demountable rims, which weighed, without hub and rim, on the average 29 pounds 7 ounces, the wood averaging 13 pounds 9 ounces, and the metal parts 15 pounds 14 ounces. Under the center pull test the ultimate strength of this size of steel wheel averaged slightly greater than that of the wood wheels of the same size. At 10,000 pounds load the average deflection of the steel wheels was .165", and the permanent set, on the average, .050". After loading to 11,000 pounds and over the average permanent set was .089". The average deflection of the wood wheels at 9,000 pounds was .557".

34 x 4 pressed steel wheels, with external clips weighing, without hub or rim, on the average 15 pounds 10 ounces, showed about the same ultimate strength as the larger 36 x 4½ wood wheels, although averaging 13 pounds 13 ounces lighter per wheel, the average deflection at 8,000 pounds being .261", and the permanent set .140".

30 x 3½ pressed steel wheels without hub or rim, averaged 9 pounds 2 ounces in weight. Three well-known makes of wood wheel, of the same size, equipped with demountable rims, weighed without hub or rim, on the average 17 pounds 1 ounce; the wood averaging 7 pounds 5 ounces and the metal parts 9 pounds 12 ounces.

Careful comparisons by both the rim and center tests were made between 30 x 3½ steel wheels and new 30 x 3½ wood wheels removed from the rear of new Ford cars, twelve Ford wheels being obtained in New York and twelve in Detroit. In the rim tests the steel wheels were slightly stronger than the wood, each averaging about 2,000 pounds, but the steel wheels, at 1,000 pounds load, deflected only 80 per cent. as much as the wood wheels. In twenty center pull tests of the same size of wheels supported slightly over 5,000 pounds, on the average; twelve wood wheels averaging about 6 per cent. less. The steel wheels at 4,000 pounds load showed an average deflection of .137", and at 4,500 pounds .180", while the wood wheels for the same loads deflected .388" and .493" respectively.

Although the wood wheels were new, with the paint and varnish fresh, and not dried out, in each test spokes broke and in most cases the felloe split. It was found that the strength of the wood wheel depended very largely upon the strength of the flanges at the hub. With ordinary flanges there was a decided dishing, which dishing continued to a lesser degree on later tests when two, three and even four flanges were placed on each side of the wheel. When cast-steel flanges were used the bolts broke and larger bolts were substituted. On the other hand, when steel wheels were tested there was very little dishing of the flanges even when only single or double flanges were used. Under extreme loads the steel wheels only bent, and all of the steel wheels tested, with two or three exceptions, were straightened and used.

In order to determine what effect bending and straightening have upon the strength of the pressed steel wheel, a 30 x 3½ wheel was given seven successive center pulls. Each time the wheel was turned over and the pull given from the opposite side. In each case the load was run up to 5,000 pounds or higher. The deflection measured under maximum load on the successive pulls were .225", .227", .724", .582", .958", .936" and .892". The deflection on the seventh pull was taken at 6,500 pounds and the load was then run up to 6,790 pounds.

A number of tests was made to determine the effect of the tightness of the rim on the lateral stability of both steel and wood wheels. These tests are not yet completed, but they seem to indicate that rim tension greater than that required for holding the joints tight is a detriment rather than an advantage, as it seems to start an incipient buckle in the spokes, which causes early serious deflection. Special fittings were made of heat-treated tool steel with knife edges. The load was applied and measured in a testing machine and the entire load then taken off by tightening the two bolts. Each test was made in duplicate up to the maximum possible with the apparatus shown which was about 9,000 pounds.

It is shown by these tests that it is possible to make a pressed steel wheel weighing only 53 per cent. as much as the usual wood wheel and its metal parts, and yet slightly stronger. This is accomplished by a design of wheel in which a large part of the metal is supplying useful strength and very little material is used inefficiently. The tests also show that a pressed steel wheel of this design weighing as much as the usual wood wheel with its metal parts, would have between two and three times the strength. Not only does this design reduce the amount of welding to about 12 feet per wheel, but it also makes possible electric welding by machine.

Other advantages of this design of wheel are the ease with which the individual spokes can be straightened in case of accident, economical and durable baked-on finish, and increased tire mileage on account of light weight and the ability of metal to radiate the heat of the tire.

The economies in manufacturing this type of pressed steel wheel are such that in quantities the prices permit of competition with wood wheels with demountable rims in the small sizes, and are lower in the larger sizes.

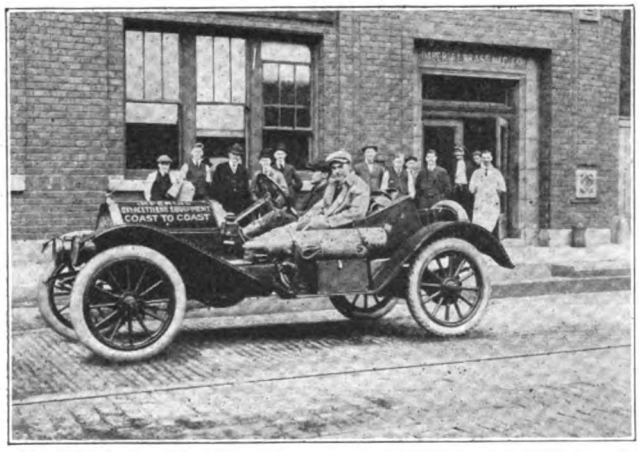
NEW AND INTERESTING THINGS IN MOTORDOM

Lubrication



Lubrication of Driving Chains.

Experience has shown that the heavy driving chains of motor cars require internal as well as external lubrication to best withstand the peculiar conditons of exposure, pressure, stress and strain to which they are subjected. A good way to secure this thorough lubrication is to first thoroughly clean the chains with gasoline or kerosene and then boil them for about 20 minutes in a bath of Dixon's Motor Chain Compound. This gives ample time for the compound to penetrate to the pins. The chains are then dipped in cold water to set the lubricant, and allowed to dry. This procedure provides for every part of the chains a friction reducing coating. It has been found that chains so treated not only resist rust and wear, but last from two to three times the life of the ordinary chain.

Garage and Repair Shop

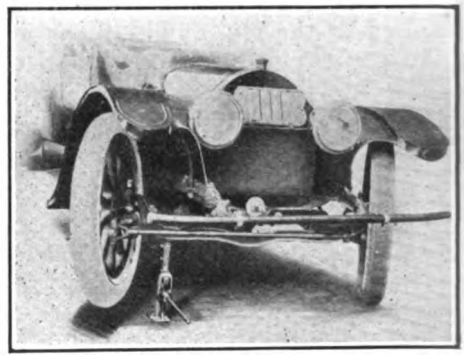
A Novel Trip.

Rather an unusual departure from the ordinary selling plan has been recently adopted and put into effect by The Imperial Brass Mfg. Co., Chicago. Recently two of their expert oxy-acetylene welding and cutting engineers started in an automobile on a "Coast to Coast" trip. The auto carries a complete Imperial welding and cutting equipment as well as supplies, and practical demonstrations of its safety and efficiency are being made in various garages and manufacturing plants in all cities along the route. Reports of their progress indicate that the trip is proving to be a big success from all standpoints, and that great interest is being displayed by all who witness the demonstrations. A most interesting feature of this "Coast to Coast" trip is the fact that these representatives have often dropped into a plant just at the vital moment when an important machine broke down, and in an extremely short time the incapacitated apparatus was put in perfect running order, in a number of instances saving for the manufacturer in time, labor and delay enough to pay for several Imperial outfits. Of course, no charge of any nature was made for this service, the demonstration merely serving as an illustration of the extraordinary and timely use for this equipment.

From Coast to Coast.

Saves Much Gasoline.

One owner of a Ford car recently, by using the Economy Gasoline Improver, manufactured by the Inst Lighter Company, of Columbus, Ohio, drove his Ford car 97 miles on three gallons of ordinary gasoline. This device uses waste heat from the surface of the exhaust pipe to heat the gasoline in the gasoline pipe before it enters the carburetor, greatly increasing the power, improving the running of the engine, decreasing the deposit of carbon and permitting a saving of about one-third of your gasoline. With this device on your car you can turn off the flow of gasoline to the carburetor one-third after the engine is warmed up, and still get full efficiency.



Portable Garage Pumps.

The model P4-ST is one of the latest models of portable garage pumps. The well known Lipman all metal four cylinder air pump model 44 is used, driven by General Electric Motor ¼ H. P. size. A gear drive is used. A fabroil pinion is used on the motor to make the drive noiseless. The gears are totally enclosed in an oil tight case which is partially filled with graphite grease. A seamless steel tank is furnished with this outfit. The tank is large enough to inflate five or six tires of average size from flat to full pressure. These outfits are provided with a patent pressure relief device which permits a much smaller size motor being used than would ordinarily be required. The pumping unit and tank are mounted on a substantial truck. Pressure gauge is furnished to show the pressure in the tank and there is also a pressure gauge in the hose line for reading the pressure in the tire.

Belt-driven pump model 44 comprises one of the well known Lipman all metal four-cylinder air pumps mounted on an iron sub-base. A positive clutch is placed between the other end of the shaft and the pump. By having a separate shaft mounted in substantial bearings, none of the strain from the belt drive is transmitted to the pump bearings, drive from the belt-driven shaft to the pump shaft being direct. This outfit is specially designed for small garages that are already supplied with power. Pump can be mounted on a shelf or on the floor and driven from line shaft. These pumps, which are illustrated herewith, are made by the Lipman Air Appliance Co., Beloit, Wis.

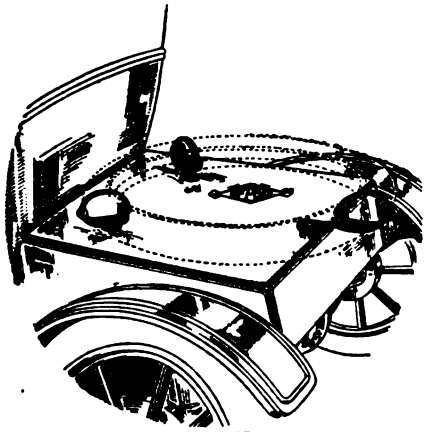
An Efficient Automobile Jack.

An automobile jack that does perfect work in any position, whether a car is stopped on a hill, in the mud, or in a rut, is usually an admirable device to carry with the car. Incidentally this jack won a gold medal from the American Museum of Safety and has a range of lifts that is all that can be desired for any occasion. It is made in four sizes and has a capacity of from ½ ton to 3 tons. It is called the Simplex jack and is manufactured by the Templeton, Kenly & Co., Ltd., 1005 South Central Ave., Chicago, Ill.

An Efficient Automobile Jack.

A Strong Accessory Line.

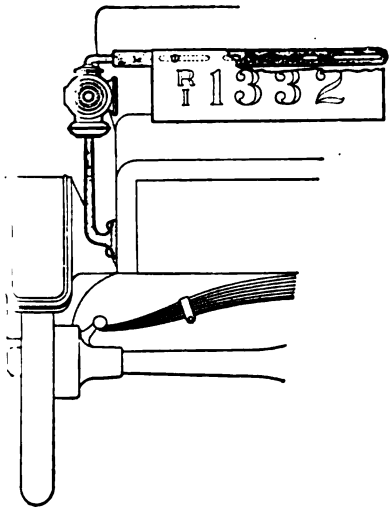
The sole distribution for the United States of the well known Angier's line of motor car accessories manufactured at Streator, Ill., has been taken over by a new company called the G & S Sales Company of the same city. This company is headed by H. V. Garvey, late of the Streator Motor Car Company and of the Spaulding Auto Company, of Aberdeen, S. D., and by J. E. Sweet, late of the Singer Sewing Machine Company and of The Excelsior Mfg. and Sales Company. The Angier specialties include the following accessories for the Ford car: Spare demountable wheel, spring radius rods, straight rear axles, radiator cradles, felt washers, fan belts and "Kant Kum Off" fan belt holder. The G & S Sales Company will cover the United States thoroughly with a chain of strong agencies.



A New Valve Repair Tool.

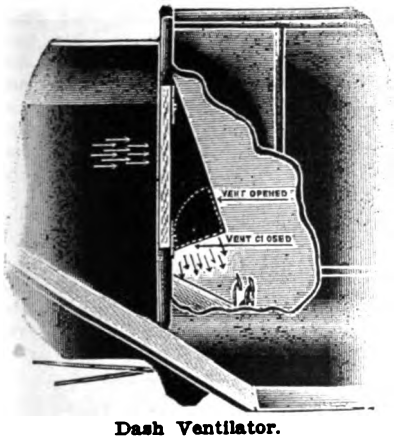
The well known firm of A. Schrader's Sons, Inc., 783 Atlantic Avenue, Brooklyn, N. Y., are now making the Schrader's universal valve tool. It is noted for the quick and proper repair of tire valves, but is adaptable for removing valves, for rethreading damaged caps, for rethreading the inside thread and for reaming out a damaged cap seat. The price is nominal and is sold to the trade in dozen lots.

Digitized by Google



Various Automobile Accessories.

Illustrated herewith are three automobile accessories manufactured by the



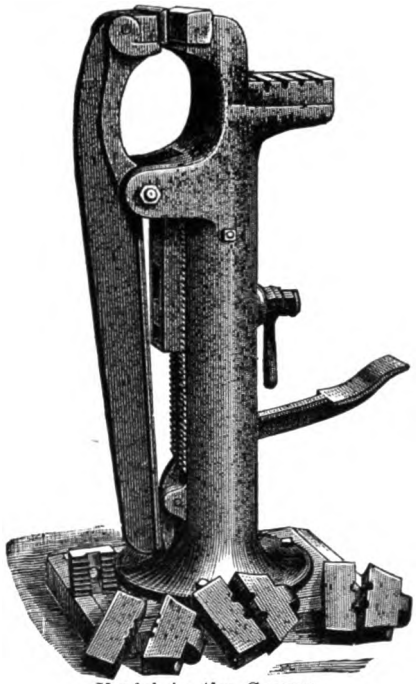
Lock Tire Holder.

Unique Findings and Supply Co., Providence, R. I. One is a lock tire holder which makes security absolute and is

Lamp and License Bracket.

guaranteed to prevent theft; another is a specially designed lamp and license plate bracket, and the last is a dash

Dash Ventilator.



ventilator. The illustrations will give a good idea of the appearance of these devices but if further information is desired it will be cheerfully given by addressing the firm as above.

A Useful Sponge.

The old saying that there is "nothing new under the sun" will not apply in the case of a new sponge, which is made of lamb's wool, for the outer casing, and is guaranteed to give longer wear and not to scratch the surface of the car in the slightest degree. It is easy to handle and used dry it serves as an efficient polisher. It is made by the Perfolam Sponge Company, 1304 East 20th Street, Cleveland, Ohio.

A Superior Vise.

B. B. Noyes & Co., Greenfield, Mass., make a foot vise and bolt holder which

Useful in the Garage.

is conveniently adjustable, simple, strong, solid and durable. The price seems to be low considering the construction of the machine and garage owners or repairmen are advised to send to the firm at the address given to learn full particulars.

Iron Cement.

A new iron cement is on the market, which is used in combination with Portland cement, for waterproofing all kinds of brick or concrete construction. It is called Smooth-On Iron Cement. It is a hydraulic chemical iron cement and is sold in powder form. It can easily be applied by any contractor and ought to be extensively used in garage construction. It is manufactured by the Smooth-On Manufacturing Co., Jersey City, N. J.

A Powerful Air Compressor.

The Au-To Compressor Co., Dept. B, Wilmington, Ohio, make an air compressor for supplying compressed air for garages, machine shops, or any other place where such work is essential. It is small, compact and requires little power to do a good deal of work. Two styles are being made, one compresses 6½ cubic feet of air per minute and the other 13 cubic feet per minute at 300 pounds pressure.

Hammered Dies.

F. E. Wells & Son Co., Greenfield, Mass., have a high reputation for making the best of screw plates. Their adjustable die is likewise a standard device. Their product is made from flat bar steel and is known pretty much everywhere among the best of mechanics and machinists.

Hood Anti-Rattler.

The Auto Parts Company, Providence, R. I., manufacturers of the well known line of Apco specialties for the Ford car, is offering the trade a new device which is sold with the Apco unqualified guarantee of "satisfaction or your money back." The Apco hood anti-rattler prevents the hood from vibrating even when the hood fasteners are not in position. One of the desirable qualities

No More Hood Rattling.

of the device is that either or both sides of the hood may be raised at the same time and they will remain in place. It is not necessary to fold the hood back as is usually done when an adjustment is to be made. Another feature is that the maximum light is afforded. With the Apco device the hood may be raised slightly to admit currents of air when operating the car in extremely hot weather, on the low speed for example. The Apco hood anti-rattler comes finished in black enamel and retails for 10 cents.

A Security Pump.

It is claimed, and with some reason, that the ordinary running of the car with the Security pump gives a water circulation of from 10 to 15 gallons per minute. Under such conditions the overheating of the motor in hot weather at

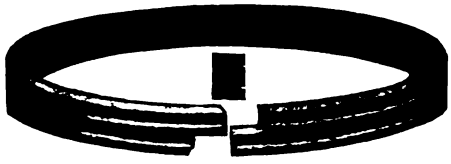
any speed or on any kind of a road is pretty near impossible. It is easily attached, of low cost, and in the case of using alcohol as a cooling liquid in winter, one filling is sufficient to last the entire season. It is made by The Security Co., 56 Terminal Way, Pittsburgh, Pa.

More Ford Specialties.

The Unique Findings and Supply Co., Providence, R. I., make several specialties for Ford cars which will commend themselves to car users and to repairmen, who find it necessary to keep things

Digitized by Google

of this sort in stock. These devices are all of low price, some of them costing not more than 25 cents, and none of them are without their good purpose for a Ford car.



Magneto Charging.

Frequently requests are received from readers concerning the recharging of magnetos. It should be generally known that this cannot be done without some device made for that purpose. Le Munyon & Bidelman, 521 Black Building, Los Angeles, Cal., make both a charger and what is called a Magnetmeter. This last instrument shows the condition of the magnets and whether they have been properly charged. The charger itself is guaranteed to charge all magnets to the saturation point. It is rather a simple operation to charge and test magnetos with these devices and repairmen will find them useful and profitable.

For the Motor

Piston Rings That Do Not Leak.

Some have raised the question of the patentability as well as efficiency claims for "No-Leak-O" piston rings. It is a well known fact, the step-lap joint is old. The patent having run out. It is also well known that grooves have been cut in piston rings for years. Some

No-Leak-O Piston Ring.

builders are now using a diagonal cut ring with a groove in the center. The claims of the inventor of the "No-Leak-O" ring is a groove between the sliding face forming the step-lap joint, and the side of the ring. The escape of gas is cut off by the step-lap joint, the oil fills the groove which forms a seal all around the ring, making the finer fit, preventing the escape of gas anywhere. The same oil lubricates and forms a packing or seal against the oil being drawn or forced up into the firing chamber. The grooves control the oil. The cylinder walls are constantly lubricated by the oil from the grooves. The grooves take up fresh oil as fast as worn out by lubrication. Carbon and spark plug troubles are eliminated. With a good dry hot spark and clean valves you will have a smooth running motor and a saving in gasoline. "No-Leak-O" rings being made in one piece out of the old standard and tried stock, made in the best manner, hold their resiliency. They will not clog up and lose their efficiency. They are easy to install and not liable to break. Made by Automobile Accessories Company, 816 W. North Avenue, Baltimore, Md.

Burd Piston Rings.

The Burd High Compression Ring Co., Rockford, Ill., has secured the contract from the Packard Motor Car Co., of Detroit, Mich., to supply the entire 1916 requirements of the Packard Company with their patented Burd High Compression Rings. The almost instant recognition that this has received from engineers and repair men has necessitated doubling the floor space and facilities of the factory more than twice within the last six months, and the Packard Motor Car Co.'s order, together with other large orders, in addition to the increasing demand from the trade for repair and replacement rings, also stocks of rings to be carried in the thirteen branch offices have already swelled the big production until now four times the former amount of floor space and equipment is necessary to meet the business.

For Scored Cylinders.

A permanent cure for scoring cylinders has been found in the judicious use of a specially prepared flake graphite. This lubricant, known as Dixon's Motor Graphite, is unaffected by any temperature encountered in the cylinder and therefore undergoes no chemical change. By the introduction of a slight quantity of motor graphite, a velvety, protective coating is formed on the cylinder walls and piston rings. The small particles of this specially prepared flake graphite fill up the minute holes and scorings that exist. This not only lessens the friction but increases the compression. It has been found that best results are obtained by the use of this Dixon Motor Graphite by inhaling a small amount in the cylinder through the air intake of the carburetor, or mixing a small quantity with the oil in the crank case, providing the engine is lubricated by splash feed.

The Guaranteed Carbon Remover.

The Orolo carbon remover is said to remove the carbon from the cylinders of any automobile in 30 minutes and to cost but 30 cents to do it. It is not likely to injure the motor in any way and does the work thoroughly. It is a liquid but when heated is immediately converted into gases which convert the carbon into a black powder or soot which may be blown out from the exhaust. It is made by the Orolo Manufacturing Co., Louisville, Ky.

One-Piece Piston Ring.

The Inland Machine Works, 802 Mount St., St. Louis, Mo., are making a piston ring of one piece only, which it is claimed has all the virtues of rings of more than one piece and no disadvantages whatever. It uncoils in expanding, thus insuring a uniform pressure and perfect contact with the cylinder walls. The firm offer to refund the price on any ring that does not give satisfaction at the end of 90 days.

Starting and Lighting

A Grand Illumination.

A jitney driver hunted for trouble with a lighted match at 1 o'clock in the morning, when his jit stalled in Philadelphia. He found it. The flame came in contact with the carburetor, lighting the gas as it flowed from the tank. Nobody thought to turn off the flow and soon the jitney was adding to the illumination of Broad Street. A friendly cop sent in an alarm, and a chemical engine got to the fire in time to save the jitney from complete wreck. The Hawthorne Mfg. Co., 35 Spruce St., Bridgeport, Conn., with their old sol electric automobile, motorcycle and marine spot lights make such an accident impossible. Send for a catalogue and learn why.

Hartman Automatic Switch.

The Hartman Electrical Mfg. Co., Mansfield, O., announces a new type of lighting switch, which is a combination device having the functions of a lighting switch and automatic circuit breaker. When installed, it may take the place of the ordinary lighting switch and fuse block, or it can be used in conjunction with the present lighting switch. The Hartman uses a solenoid which operates a toggle arrangement, and should there be an accidental ground in the system, the circuit cannot be re-established unless the cause is removed.

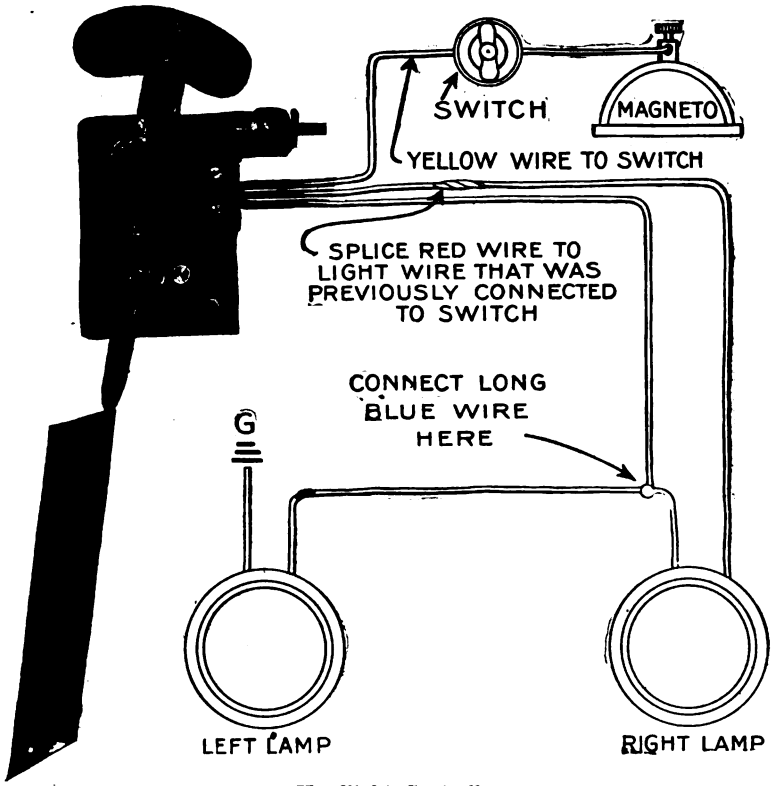
Lamp Specialties.

The illustration shows an oil fount or container as used in automobile lamps on Ford and other low-priced cars. We understand that these are often lost off by motorists and replacements are required. The oil-fount shown is of an approved standard style and pattern and it was manufactured by Collins & Co., 150½ Elm Street, Amesbury, Mass.

Oil Fount for Oil Auto Lamps.

This is a new firm in the automobile field, but they may be classed as lamp specialists, and they are prepared to make or repair any kind of automobile lamps or lamp parts and fittings, including reflectors, etc., in large or small quantities. Estimates will be gladly furnished on any work where metal spinning is required. The proprietor, William A. Collins, formerly held a prominent position with the Castle Lamp Co., and is competent, by many years of experience, to handle work of the character indicated to the best possible advantage.

Old Sol Spotlights.



There is nothing more conducive to safety and cheerfulness than light, either artificial or natural. No matter whether you are at home or on the street, darkness is not pleasant, and if you are in an automobile a proper light is an element of safety, not only for yourself but for others. The Hawthorne Mfg. Co., of Spruce Street, Bridgeport, Conn., make what is called the Old Sol Spotlight for automobiles. It can be turned at any angle, either front, back or sidewise. It is guaranteed to be satisfactory in every way and those who do not already have satisfactory lighting arrangements for their cars might find it convenient to consult this firm and learn all about the Old Sol Spotlights.

Ford Magnetos for Lighting.

The New York Coil Company, 338 Pearl St., New York City, N. Y., manufacturers of the New York Uni-Coil Ignition System, master vibrators, and other well known Ford accessories have recently placed on the market their New York Head Light Controller for Ford cars. This device is unusual in construction and the makers claim causes a Ford magneto to deliver a brilliant strong light when operating even at the lowest speeds at which the car can be run. The most novel feature of the device consists in the principle of utilizing the entire electrical output of the Ford magneto at all speeds below approximately fifteen miles per hour for the one headlight located on the left hand side of the car. Above this speed the two lights come into operation and at still greater speed a resistance is automatically thrown in the circuit to prevent the lamps becoming burnt out at high speeds. Every operation of the device is entirely automatic, the driver having nothing whatever to do after once installing the system. The device depends for its operation on the draft of air created by the fan, the instrument being placed about eight inches to the rear of the fan where it is secured to the top of the cylinder by means of one of the cylinder bolts.

An arm which is counter-weighted carries on one end an aluminum disc, this disc is in line with the left hand half of the fan. The air from the fan causes this disc to move away from the fan in direct proportion to the speed at which the engine is revolving. An adjustable spiral spring tends always to operating the arm and disc in the opposite direction. The arm carries a contact, which forms a sliding connection or contact on three similar contacts secured in the solid metal base. When the engine is turning at speeds below fifteen miles per hour the arm establishes connections to the one left hand lamp. As the speed increases to a point where the magneto is able to supply the two lamps with current to give the proper candle power the air draft from the fan is sufficient to move the arm to the second contact, which cuts in two lights. At still greater speed as before described the device causes the current to travel through a resistance coil, which while not diminishing the lights perceptibly introduces sufficient resistance to prevent their being burnt out. The makers advise us that they are turning out these devices in very large quantities, the purchasers of which are most enthusiastic over its operation.

Headlight Controller.

A Low Price Oxy-Acetylene Apparatus.

The Searchlight Co., 1014 Karpen Bldg., Chicago, Ill., make an oxy-acetylene welding apparatus that is easily operated, reliable and guaranteed to give complete satisfaction. The time is coming when no repairman or garage will be without an apparatus of this kind. When one can weld a broken car frame in less than an hour, it does not pay to send the work to some firm outside, or to delay in making the necessary outlay to secure such an outfit. This firm makes an apparatus which they are selling for $50. They have branches and refilling stations located conveniently at various points all over the country.

Stops Lamp Glare.

The E. G. Staude Mfg. Co., St. Paul, Minn., has for years made a successful box steeling machine. This company has a large well equipped plant and for over a year has been experimenting with the Staude Glare Stopper. The original design placed the glass in a metal ring and clamped it to the shield with two screw supports. While it does not in any way compare in quality and appearance with the present model, it became popular last summer. The amber glass used on the first model was imported from Belgium, and when this source of supply was shut off the manufacturers for a long while felt that the progress of the business was stopped. A search, however, revealed the fact that even a better quality of amber glass could be obtained in America, and when this glass was found it tested with so much strength that the manufacturers eliminated the rim, making the Staude Glare Stopper with a ground lens edge and greatly improving its efficiency.

Prest-O-Lite Batteries.

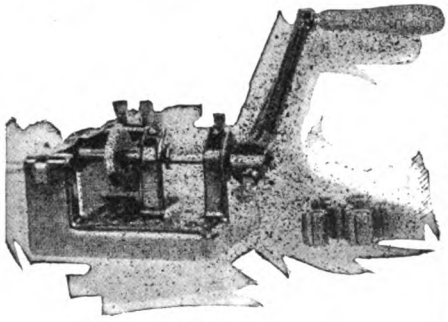
The entrance of the Prest-O-Lite Company, Inc., of Indianapolis into the electric lighting field has just been announced. The company is now manufacturing the Prest-O-Lite storage battery. Of no less interest will be the fact that The Prest-O-Lite Company, with its famous system of service, including thirty-five factory branches and more than 20,000 agencies throughout the country, aims to place behind the Prest-O-Lite battery a system of service of unusual character and scope.

The company states that its new interests will in no way interfere with the extension of its business in the well-known Prest-O-Lite acetylene system. Notwithstanding the popular impression that the widespread use of electric illumination on automobiles has adversely affected the gas-lighting industry, The Prest-O-Lite Company states that the use of gas lighting in automobile practice is to-day larger than ever before and is still growing.

However, instead of pursuing the controversy between the electric and gas factions in the automobile field, with which most motorists are familiar, it will be apparent that The Prest-O-Lite Company has placed itself in position where it can not only furnish either kind of illumination, but can also furnish the extensive Prest-O-Lite service on either kind.

The Prest-O-Lite storage battery is designed as a distinctive type in the battery field. While embodying nothing that is revolutionary, the design will include features upon which strong claims of increased current capacity, in connection with decreased weight, will be based.

As a part of its activity in its new field, The Prest-O-Lite Company on June first purchased and absorbed the entire business, assets and patents of the Pumpelly Battery Company of Indianapolis and has incorporated in the new Prest-O-Lite battery many features of the more recent Pumpelly types.



Temporarily, the Prest-O-Lite storage battery will be manufactured in the old plant of the Pumpelly Company. The present factories of The Prest-O-Lite Company are quite fully engaged under the load of the company's acetylene business, which has extended into many fields outside of the automobile industry, such as oxy-acetylene welding, house lighting, and many other new commercial applications of acetylene. New buildings will be erected shortly at the Speedway plant of The Prest-O-Lite Company in Indianapolis, in which the new Prest-O-Lite storage battery will be manufactured on a large scale. The company's battery line will include ignition, lighting and starting batteries of several types. The present output of the Prest-O-Lite storage battery is about 400 per day.

Carburetion and Ignition

A New Valve Seat Tool.

The Adjustable Valve Seat Refacing Tool can be adjusted to any size valve seat in less than half a minute, and by a few turns will give a perfect seat. This tool is furnished with four different size pilot stems to fit the different size valve leads which makes the valve seat come positively true with the valve

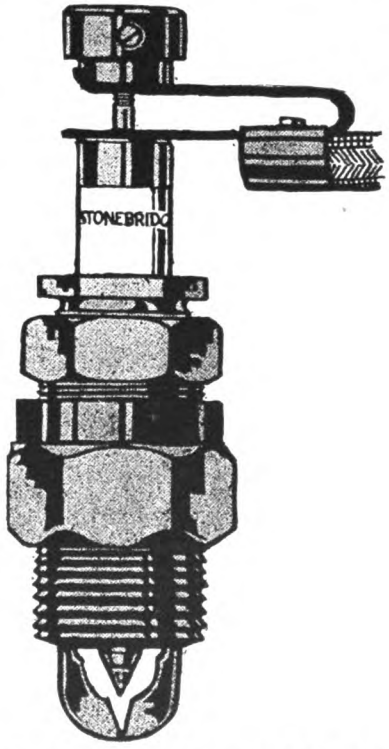
For Valve Facing.

stems, as in many cases the valve seats are worn eccentric or oval causing a knock in the cylinder which cannot be overcome by grinding alone. This tool is made in two sizes to take in all valves from motorcycle size to three inches inclusive. This tool will be found very valuable in garages, repair shops, or to any one desiring to true up their valves before grinding. It is made by the American Valve Tool Co., 589 Hudson Street, New York.

Champion Spark Plugs.

In order that the dealers who have not as yet signed the profitsharing agreement of the Champion Spark Plug Company may have further time to take advantage of that opportunity, the time limit for their acceptance by the Company has been advanced from June 1st to July 1st, 1915. It is recalled that when the first announcement was made to the trade, attention was called to the dealer that all he had to do was to fill out the blank which had been mailed to him or which he could procure through his jobber's salesmen. At the end of the year the Champion Spark Plug Company would send the dealer a check representing his pro rata share of the profits which he had earned, and which would be based upon the number of Champion spark plugs he had purchased during the year. It was pointed out that it was not necessary to handle these plugs exclusively in order to participate in the profits, though he must take the number of plugs he enters on his card.

Storage Batteries.



The history of storage battery engineering in America would be incomplete without mention of James K. Pumpelly. To him probably more than any other electro-chemist are due epoch making discoveries in the commercial manufacture of the lead type accumulator. Mr. Pumpelly devoted more than thirty years of his life and his own private fortune to storage battery research. Up until his death a few days ago, Mr. Pumpelly was at the factory every day supervising the manufacture of the electric storage batteries which bear his name and bringing them to their present state of perfection. But even Mr. Pumpelly's discoveries would be of little value unless they were applied in the most scientific and careful manner. To this end the Pumpelly Battery Company has installed the latest laboratory devices for testing both the finished product and the raw material. They have borne in mind the vital importance of good workmanship. To-day the Pumpelly Battery Company is making storage batteries of all types and their product has made for itself an enviable reputation for high voltage, ample capacity for cold weather service, low heat characteristics, small loss of charge on standing and a generous ampere hour rating that is very valuable in motor car lighting and starting.

A New Ford Carburetor.

The Brad-Kent carburetor, made by the Frost Mfg. Co., Kenosha, Wis., is unusually efficient in the matter of gasoline saving and it is claimed will save two gallons out of every five. So confident are the manufacturers of its superiority that they offer to send it on a thirty days' free trial. On a recent test made on country roads it consumed only one gallon of gasoline for every 33.12 miles. The firm refers to the commercial agencies as to their responsibility. It has but a single adjustment and is extremely light and simple. Like almost everything else of value the merit of the carburetor consists of the results it gives.

The Stonebridge Spark Plug.

This plug can be cleaned without removal from the car. It never needs ad-

justing. The entire porcelain can be removed and replaced, while plug proper stays in motor. It has special safety connection on the terminal. You can test out the plug without the use of any tool. The spring terminal always assures positive contact—not sometimes, but always. It is made by the C. H. Stonebridge Mfg. Co., New York City.

For Displaying Spark Plugs.

The Fulton Co., 726 National Ave., Milwaukee, Wis., is supplying an attractive spark plug display stand to dealers who purchase a stock of their Eklips spark plugs. Places are provided for six spark plugs and it may be set on show cases or in show windows. There is no

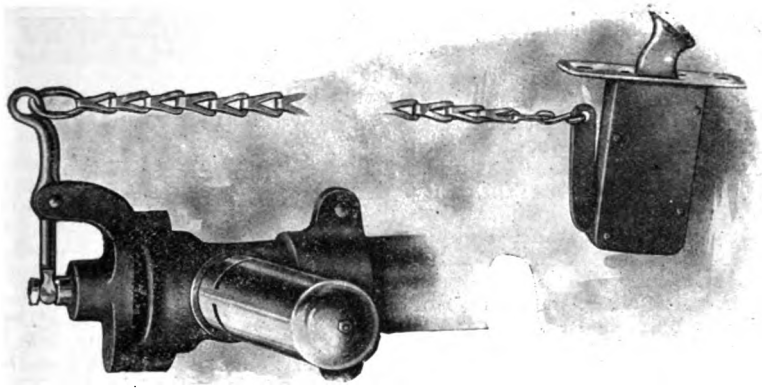
use in having goods of any kind unless they are suitably displayed and this seems to be an excellent device for this purpose.

Care of Spark Plugs.

The L. F. Benton Co., Vergennes, Vt., has issued a booklet on spark plugs and how to make them give perfect service. The booklet is copyrighted, and right here it may be stated that there is no reason whatever why this should be, since the more it is quoted the better for the Benton plug. But in point of fact the Benton plug is like truth—"it needs no ornament." It may not be the best one on the market, but that it is a mighty good one all who have used it will gladly admit. Incidentally, this booklet shows how important it is that spark plugs be kept free from soot, and why the popular test of laying a plug on the engine and watching the spark is misleading, for the reason that the voltage required to pierce the gap under compression is from 8 to 15 times that required in the open air. But it contains much other useful information, and drivers and garage men ought to read it.

The Critchley Reamer.

The Critchley Expanding Reamer is particularly adapted to the requirements of the automobile repairmen. The ordinary Expanding Reamer made by all standard manufacturers has an average expansion of .005 inches which is less than 1/64 inch. When the repairman has an oval hole to ream that measures on its largest a diameter more than .005 in excess of its nominal diameter he is absolutely "up against it." There is nothing for him to do but drill it out and then use a reamer of a larger size. In this way, he gets an exact fit, it is true, but it is more than likely that he has weakened a part that did not have any material to spare in the first place. With the Critchley Reamer he has an expansion of 1/16 inch or more to a size. It only requires a minimum investment on the part of a repairman to be ready to tackle any job that comes into the shop. This reamer is not intended to take the place of the Rose Reamer, but



Digitized by Google

it is adapted to take care of the numerous jobs demanded of the everyday repairman in the highways and byways of our country. In addition to all the qualities of this tool, it is carefully manufactured by high grade mechanics under the most careful inspection. The manufacturers are Chadwick & Trefethen, Portsmouth, N. H., and the Caldwell Sales Co., of San Francisco, are agents for the Pacific Coast.

Body and Top

A Warning Signal and Theft Protector.

We illustrate a novel device which serves two purposes. It is not only a loud and effective warning signal, but it also protects the car from thieves. When leaving the car, you simply take the key with you which leaves the whistle open so that your engine cannot be started without the whistle blowing loud enough to be heard blocks away, thus attracting attention to the fact that some one is running away with the car.

The American Auto Whistle.

The mechanism of this warning signal which is called the American Auto Whistle will be understood by studying the illustration. This whistle will blow for you as long as your engine goes with just a kick of your foot, thereby giving you the use of your hands and feet in case of accident. The manufacturers also claim that this is a self-cleaning whistle and it will tell you if a cylinder is leaking or skipping on your engine. This decidedly novel invention is manufactured and sold by Alfred H. Clark, 1307 Howard Ave., Bridgeport, Conn.

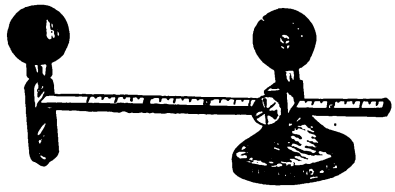
New Ford Body.

There is a constant demand for commodious bodies for Ford cars that will carry the number of passengers that the Ford car can easily handle. L. M. Cotton, Inc., Boston, Mass., makes a body for business or pleasure, with top that has three seats, two seats or one seat. They also make this same body without top. It will fit a Ford car or can be put on a chassis of other cars if required. It is made by a firm that has been building carriage bodies for years and years, and in construction and appearance it is difficult to see how it can be improved. The price is remarkably low considering its quality and capacity. Incidentally, this firm makes bodies for almost any purpose and it carries more than 50 models in stock.

One-Man Automobile Top.

The Hercules Rubber Co., 2 Hudson St., New York City, make an automobile top, including a dust hood, that is easily handled by one man. It is made of various material as desired, is sold at a low price and can be supplied for use upon almost any car that is manufactured. If any of our readers desire to secure one of these tops they should state the name of their car, the model and year, and also whether silk, mohair, khaki or imitation leather is desired.

New Car Fender.



The Glasgow combination bumper and safety fender is the invention of a Philadelphian, Samuel Glasgow. The need for such an appliance was forcibly impressed upon him through a sad accident while motoring, and he determined, if possible, to atone for the mishap by producing an article which would, as nearly as possible, make repetition of his experience avoidable. He has been several years developing the device and has now succeeded in bringing it to a point of perfection warranting the placing of it upon the market. It can be readily attached to any make or style of automobile, and when not in use as a life-saving device appears simply as a high-class bumper, and as such is alone invaluable; the method of connection with the car, clamping the spring, abutting the axle, absolutely prevents contact with the chassis or spring; in this way alone saving injury to the car and consequent motor repair bills. When desired for the purpose of saving lives, the fender may be instantly released by the pressure of a button, covering the entire front of the car from the top of the wheel to within two inches of the ground with a flexible canvas pocket so cleverly arranged and adjusted that it will pick up any object in its path and carry it until the car can be brought to a full stop.

A Low Priced Signal.

A few years ago a horn that sold at $3.50 and was guaranteed for three years would have been considered a miracle. The Service Motor Supply Co., Washington Blvd. and Desplaines St., Chicago, Ill., make such a horn, and if it does not give entire satisfaction the cost will be refunded upon returning it.

Red Devil Glass Cutters.

Automobile headlights differ greatly in size. As a result, many garages and repair shops feel that they must keep on hand a good stock of headlights in a large variety of sizes. There is really no need to tie up money like this. Circular glass cutters easily cut headlights and it is inexpensive when done with a reliable tool, for example, like

Red Devil Cutter No. 263.

the Red Devil cutter No. 263 shown here. It has a genuine hand honed steel wheel, tested and inspected by an expert. It cuts circles from 2 to 22 inches in diameter. It has an all-steel base with a rubber bottom to prevent slipping. The adjustable cutting rod is highly nickel-plated. The tool works as well as it looks. It is made by Smith & Hemenway Co., Inc., 179 Chambers St. It costs more to do without this tool than to buy one and use it. The tool also makes a profitable article which garage owners and supply dealers can sell to the motorist who wants to do his own tinkering.

Turns Dust and Water.

A hard, dry wax applied to the body, hood and fenders of automobiles, electrics and limousines is now being used as a preventive of harm to car surfaces from contact with dust and water. S. C. Johnson & Son, of Racine, Wis., make an ideal wax for this purpose. It has a peculiar hard, slippery quality that prevents both dust and water from sticking—they slip right off the delicate, highly polished surfaces before any rough gray spots are formed. Johnson's Prepared Wax is really a splendid wax for car surfaces. It imparts a high

gloss which holds its luster indefinitely because of its hard, dry, impervious nature. Covers up small scratches and certainly does a great deal toward keeping the surface of cars in good condition generally, which, incidentally, saves a lot of labor for caretakers. The extraordinary protective and preservative properties are equally effective on car surfaces of either high or low degree.

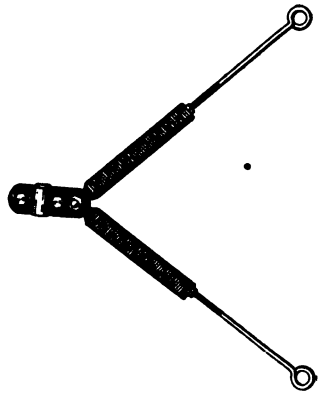
Digitized by Google

The Seiss Horn.

When one purchases a signal it is desirable to get the best, when it can be bought at a low price. The Seiss horn is double acting and it gives a loud, commanding warning signal. It is easily operated and is sure to command the attention of any one who is before it. Even women, cows and chickens are sure to get out of the road when they hear its blast. It has a ten year guarantee. The price is extremely low and the mechanical construction is of the very best. It is made by the Seiss Mfg. Co., 443 Dorr St., Toledo, O.

To Hold the Stars and Stripes.

M & M Bracket, 29 East Third St., Cincinnati, O., make a flag holder, which will probably be popular just at the present time. A good many car owners like to show their colors in driving and this device for carrying a flag on the front of the car is simple and of low price. The same firm likewise makes a bracket for carrying the license.



The Running Gear

New Automobile Tires.

The Northland Rubber Company, 703 Northland Ave., Buffalo, N. Y., is prepared to give an exclusive agency for the Northland tires. Only one dealer in each town will be given this agency and only responsible dealers need apply. But the firm that gets this franchise will find that it is a paying proposition.

A New Ford Steerer.

A new steerer for Ford cars, that it is claimed prevents side sway, and makes steering very much easier, is on the market. It is made of the best material, and is adjustable according to the

Makes Steering Easy.

condition of each car and to suit the owner's idea or requirements. The illustration gives an idea of its construction. It is made by Chas. Friedlander & Co., 58 Warren St., New York.

A Useful Steering Device.

The Savidge steering device for Ford cars is simple, easily attached and makes driving easy, and it likewise acts as a shock absorber. It is made by the Savidge Steering Device Co., 508 Murphy Bldg., Indianapolis, Ind.

The Temco Shock Absorber.

One model of this shock absorber is especially made for Ford cars. They take the rebound from the springs gradually and thus prevent sudden or violent jars or jolts. An unlimited guarantee is given with these shock absorbers that they must fully, thoroughly and completely satisfy the purchasers, or money will be returned. The firm likewise makes a Universal shock absorber for all cars, an improved master vibrator and a portable electric drill. For full information address the Temco Electric Motor Co., 2115 Sugar Street, Leipsic, Ohio.

New Non-Skid Tread.

The Marathon Tire & Rubber Company announce the perfection of a new type Non-Skid Tire Tread. The innovation does not pertain to the anti-skidding qualities of the tread but has to do with the wearing qualities. It is the general custom of tire manufacturers to build the non-skid tread far down on the sides of the tires where it does not come in contact with the road—in consequence when the tire is worn out a considerable portion of the tread remained unworn. The New Marathon Tread is trade named the "Concentrated" and is exactly what the name implies. All the material is heaped up in center where it will come in contact with the road. It is estimated that this new type tread will increase the mileage 25 per cent. A patent has been applied for.

A Great Record.

On May 18th, E. G. Baker of Indianapolis, driving a Stutz Bearcat Roadster, established a new ocean to ocean record when he completed his trip of 3,728 miles from San Diego, Cal., to New York City in 11 days, 7 hours and 15 minutes. Mr. Baker drove the entire distance himself, this being the first time a record transcontinental trip has been made by a single driver. Mr. W. F. Strum also of Indianapolis, accompanied Mr. Baker and checked the car at all night stops on an official book which he had stamped by different post office and city officials. On his trip Mr. Baker used Easyon Tire Chains made by the Leather Tire Goods Company of Niagara Falls, N. Y. Mr. Baker states that on account of the ease and quickness with which he applied these chains he was able to save considerable time whenever it became necessary to use chains to drive through mud holes or other places where he could not obtain traction with bare tires. Mr. Baker carried no other chains on the trip and states he found Easyon Chains absolutely fulfilled his every requirement. The previous record from Atlantic to Pacific was 15 days, 2 hours and 15 minutes so the new record cuts off nearly four days from the previous time.

A New Inner Tube Plug.

The Sampson feather-edge inner tube tire plug is for punctures and small blow-outs. It is claimed that repairing a tube with this plug is easier and quicker than it can be done by any other method. This plug is made of pure soft rubber and is naturally extremely elastic and thus easy to insert. It is guaranteed never to leak, nor to affect the shoe in any way. The manufacturers are supplying dealers as rapidly as possible but they prefer that the plug should be bought of the local merchant if possible. If it is impossible to do this, however, they will sell an outfit direct and prepay cartage charges. It is made by Stevens & Co., 375 Broadway, New York City.

Bailey Gearless Differential.

The New Process Gear Corporation of Syracuse, N. Y., has entered into a contract with the Gearless Differential Company of Detroit to manufacture the Bailey Gearless Differential for the general automobile trade. The arrangement was made after the most thorough and exhaustive tests by the New Process people, and after their engineers had reported it to be "the first important improvement in the standard type of differential in 15 years." The New Process Corporation will immediately inaugurate a thorough campaign to interest manufacturers, a number of whom have already arranged for tests. The parent company will continue its present policy of going after the replacement business on cars already in service. This has already reached large proportions, especially among Ford owners.

A Tire Repair School.

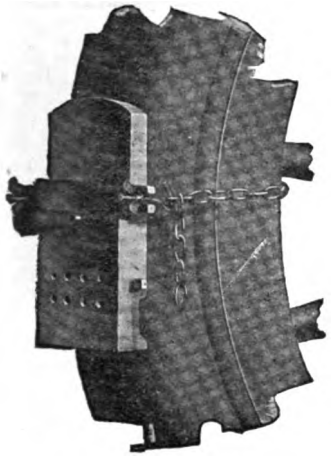
Eight years ago the Clouse Tire Repair School was started in a little building 30x30 feet, in Cleveland, O. To-day they are occupying a building 50x190 feet, two stories in height. This could not have been accomplished unless they were proving the value of the school. No text books are used. They teach by practical demonstration with proper equipment and by lectures. The reliance the student places upon text books would be such as to have him overlook real practical facts, while the practical demonstration was being made. The equipment is so complete, covering every phase of the tire repair business, and the course of lectures so thorough that the impression is made so forcible, that the use of text books would only tend to confuse the student's mind. It is simply necessary for the student to apply himself to his work and listen to the lectures to become fully acquainted with every phase of the tire repair business. There is but one real tire repair school in the country and that is the Clouse school at Euclid Avenue and 90th Street, Cleveland, O.

A New Tire.

The plant of the Century Tire & Rubber Co., of Plainfield, N. J., has been purchased by Leon Jaffess, of New York City, who owns a tire factory in Harrison, N. J., in addition to his salesroom in New York. Mr. Jaffess paid $29,000 for the Plainfield plant and will utilize its 60,000 square feet of floor space for the manufacture of a new tire.

A Unique Car Bumper.

The Concrete Bumper Company, 214 West 50th Street, New York City, make car bumpers in all sizes of round and square type. They are filled with concrete and reinforced with a steel rod running through the center. They furnish absolute protection for car radiators and lamps and are said to give the best of satisfaction in every way. The firm likewise makes rear bumpers and bumpers for ambulances and trucks.



A Safety Steering Gear.

Occasionally complaints have been received that the Ford car is rather hard to steer on rough roads. With this in view C. C. Rounds & Co., of Dows, Ia., have brought out a steering gear that is said to make the Ford steer just like a big, heavy car. It is especially desired if a woman is driving.

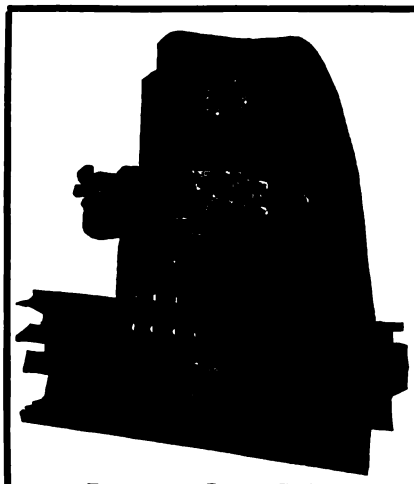
WIZARD AUTOMATIC STEAM VULCANIZER



NEW PRICE ONLY $3.50, BY MAIL PREPAID

Repairing Casing

By manufacturing these vulcanizers in such mammoth quantities we are now able to sell them at only $3.50—you can save this amount in repairing just a few tires.

Don't ruin your casings by neglecting those small cuts—they mean the loss of real dollars to you. Vulcanize them full of new rubber, and MAKE THEM LAST TWICE AS LONG. Ask any tire manufacturer if this is not so. The small cuts admit water and sand to the fabric and the tire soon blows out at this weakened spot.

Repairing Inner Tube

10 DAYS' FREE TRIAL We will ship this vulcanizer by mail prepaid. Try it for ten days and if you are not entirely satisfied, return it, and we will refund your money.

The WIZARD AUTOMATIC STEAM VULCANIZER is adapted for BOTH TUBES AND CASINGS OF ANY SIZE. It is a metal body filled with water at factory and never needs refilling. Steam generated by a small flame which is entirely enclosed. Burns gasoline with a blue flame and no smoke. Heat is automatically controlled. Requires no watching. Vulcanizing face (curved to fit casing) 3 x 6 inches. The Wizard is highly polished and nickel plated. Can be used on the road or anywhere. Pays for itself in a short time and will never wear out. Thousands in use. ANY BOY CAN EASILY OPERATE THE WIZARD. Sent by mail prepaid, upon receipt of the price. Full instructions, rubber, shears, cement, etc., furnished with each outfit. Remember, money back if not entirely satisfied.

PRICE COMPLETE, PREPAID, $3.50

Manufactured by

The National Motor Supply Co.

5636 Euclid Avenue CLEVELAND, OHIO

Branch Office, 2204 Michigan Avenue, Chicago, Ill.

Enclosed find money order for $3.50. Send me by mail prepaid a Wizard Steam Vulcanizer. You agree to refund my money if I am not satisfied after ten days' trial. (Write plainly.)

Two New Tire Tools.

The Racine Tire Tool Co., Superior and Prospect Streets, Racine, Wis., announces two tools for use especially in tire repair shops, but also of value to the car owner who has much tire repair work to do. One of these tools is in the form of a small portable electric motor with a grinder attached, the latter being used for preparing a cut before repairing it. The wheel for grinding is about the size of a 50-cent piece and makes a neat job of the cut, doing away with much sandpapering, etc.

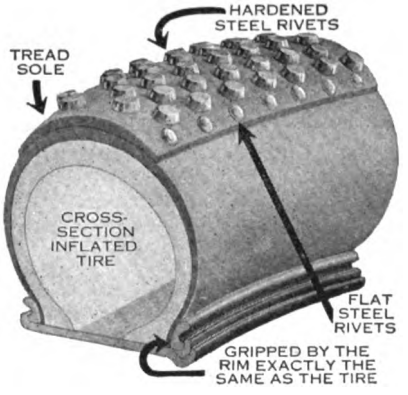
Frictionless Shock Absorbers.

A frictionless shock absorber naturally has a longer life than one that is actuated by friction only. The Halladay frictionless shock absorbers are guaranteed, and they are made by a reliable firm which backs its claims with confidence. They are well made and suited for all types of automobiles. It is worth something to ride in an automobile and not have the nerves and bones shook up to such an extent that riding is a discomfort. They are made by the L. P. Halladay Company, Streator, Ill.

New Rim Contracters.

A new rim contracter, for the straight sided split rims of the Kelsey and Stanweld types, is now ready for market. It is strong and adaptable for all sizes of these rims. This tool is low priced and those interested would do well to write to the manufacturers for full information.

New Tire Boots.



In view of the growing demand for tire boots the Leather Products Company, of Denver, Colo., has recently added four new tire boots to their line—one of them is illustrated herewith. They are made of the best selection of "Elk" tanned leather, treated and waterproofed by a secret method. The body is cut from finished stock and is reinforced on the tread porton with an extra wearing sole of "Elk" leather, which is closely studded with flat head steel rivets to take the wear. This boot is guaranteed not to creep or slip on the tire and will stand hundreds of miles of road wear. It is made in both hook-on and strap styles. All inquiries should be addressed to the manufacturers, who will gladly send complete details and prices.

The Peerless Boot.

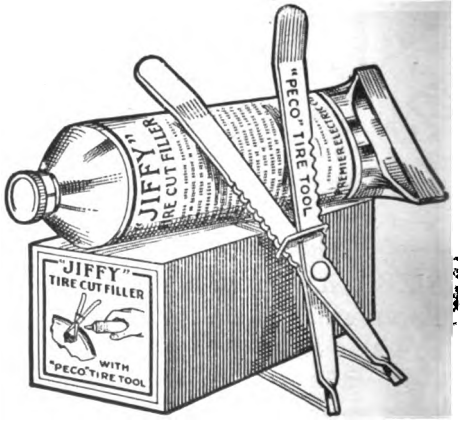
New Durable Tread.

The Colorado Tire and Leather Co., of Denver, Colo., has recently perfected a new Durable Tread—this tread, while built along the lines of previous Durable Treads, is in many respects entirely new. The cross section illustrates the principle of their construction. The tread consists mainly of one continuous band built up of several layers of rubberized fabric, extending entirely over the tire from bead to bead and fitting as tightly as a glove—thus preventing slipping—or sand and moisture from working in. On the outer surface of these layers of fabric is riveted the tread strip, or wearing sole; that is the part of the tread that comes in direct contact with the ground and takes all of the road wear. This wearing sole is built of a layer of extra chrome leather especially tanned and waterproofed so that it will withstand the most severe conditions of service. The wearing surface is studded with sharp edged hardened steel rivets, the entire protector making a covering of only one-half inch in thickness.

A New Inner Tube.

A new pneumatic tire which seems to be both desirable in saving time in making repairs and economical, has been invented and patented. It is called the Anti-Pneu-Matic inner tube, and G. V. Baillard is the inventor. Instead of one continuous inner tube, from 12 to 20 small sacks or inner tubes are used, each 4 inches long, making a continuous inner tube around the wheel, and all are contained within the tire shoe. Each section is secured to a valve every four inches on the wheel, each of which is mechanically opened by turning a control stem. Then the air is pumped through the main valve, as is used at present, until the sections are filled to the air pressure required. If a puncture is received one of these little sections collapses but the adjoining sections expand lengthwise 2 inches, and thus take the place of the 2 inch section which has collapsed. Of course this somewhat reduces the tire pressure, but it is stated not to be noticeable, and claims are made that six of these sections may be punctured before it is necessary to stop the car and put in others. By using these tire sections one is pretty sure to arrive at his destination without having to stop for tire repairs, no matter how severe the puncture may be. After one has arrived at home he can put in new ones in about five minutes, and of course the new section does not cost anywhere near the price of an ordinary inner tube. It is likewise claimed that if a blowout occurs with these inner tube sections, although the section underneath may explode, the others will not, but will merely fill up the aperture caused by the one that has exploded. The device is rather interesting, and although, as we understand it, the manufacture h not yet begun, it is expected that th will soon be for sale on the mark For full information address G. V. B lard, 251 East 31st St., New York.

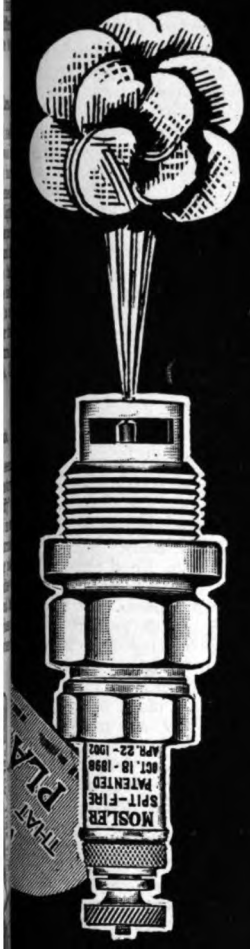
Tire Carriers.



The International Stamping Co., 18 Austin Ave., Chicago, Ill., make thr different styles of tire carriers, any o of which can be attached to a car in half an hour or less. There is a rig way and a wrong way to carry ext tires and these carriers exemplify clear to any one that they are using the rig way. They seem to be well finished a they are made in so many different siz and styles that one is sure to fit an car that is made.

Wheels for Ford Cars.

It is claimed that pressed steel wheels are stronger than either wood or wire. As far as we know no one has yet attempted to deny this statement. It is also stated that they are lighter than ordinary wheels and consequently require less power to propel and that they have a better appearance than other wheels. They can easily be installed on a Ford car and in case of a change of tires can be made in two or three minutes. They are manufactured by the Hydraulic Pressed Steel Co., Cleveland, Ohio.



Fills Up Tire Cuts.

The "Jiffy-Peco" outfit seems to fill a long-felt want of the motorist as it consists of a tube of "Jiffy" tire cut-filler and a "Peco" tire tool in one outfit. The large tube of filler furnished with this outfit is a quick-curing plastic gum compound that quickly unites with the rubber, making a tough and lasting repair and if used to fill glass cuts and nail punctures in casings when these are fresh it means more miles to the tire-life and consequent saving to the motorist. The "Peco" tire tool, as furnished with this tire cut filler completes the outfit and enables the motorist to open up and properly clean the cut before applying the filler, for it is essential in making casing repairs to see that they are properly cleaned of all dirt and grease and this can only be done properly when one has the use of a tire tool designed especially for this purpose. This outfit is manufactured by the Premier Electric Company, 4038 Ravenswood Ave., Chicago, Ill., who have an attractive proposition to offer dealers.

Tire Tubes and Casings.

The Norwalk Tire and Rubber Co., Norwalk, Conn., are looking for dealers to take the exclusive sale in their own localities of their tire tubes and casings. These tires have a good reputation.

A New Vulcanizer.

Lee C. Mapes, 16 Fulton Ave., Rochester, N. Y., is putting on the market a new vulcanizer, which is the outcome of much study and experimenting. It is large enough to repair anything in a tire, low in price and is designed for the car owner as well as the repairmen. It is made in varying sizes and styles and in quite a wide range of prices, thus being suited for large repair places as

Mapes Vulcanizer.

well as those owning but one car. According to reports from users it has given the best of satisfaction. With these vulcanizers is sent a catalogue or circular that those using them or doing vulcanizing of any sort will find instructive and useful. Each machine is guaranteed for six months, and if repairs are necessary they will be made at reasonable prices, and new parts are always furnished at a low cost.

Business Notes

Colorado Road Guide.

The Colorado Automobile Directory contains 144 pages of corrected road logs and touring information which will be much sought after by the traveling motorist. The book is published by The List Publishing Co., 615 Denham Bldg., Denver, Colo.

Eight-Cylinder Oldsmobiles.

The Olds Motor Works announces for the 1916 season two lightweight cars, an Eight and a Four, both weighing well under 3,000 pounds, the former listing at $1,295 and the latter at $1,095. The new Eight was designed primarily to satisfy the market hitherto supplied by the big Olds and also with a view to creating a new market for a machine selling under $1,500 with quality as its chief attraction. With these objects in view the company decided to introduce a car of high power and smoothness of operation—qualities which were found to be best secured in an eight cylinder car.

The Argo Car at $385.

Marketing and use of the 44-inch tread Argo having proved the worth of the design, the Argo Motor Co., Inc., of Jackson, Mich., is now offering a new machine built along much similar lines, but with a standard 56-inch tread. This is known as the Argo "Standard," and may be had in a five-passenger touring car at $435, and a roadster at $385, both fully equipped save for an electric starting and lighting system, which may be had for $60 extra. Production of the car for the 1915-16 season has been set at 20,000 cars.

Ford Rebate Checks.

If 30 men worked 30 days, giving away money at the rate of $50 a minute, at the end of the time they would have disposed of $15,000,000. That is the calculation of the Ford Motor Co., which has set 30 men making out the rebate checks that are to go to Ford owners who bought their cars after August 1 last.

Duryea Trucks.

Charles E. Duryea, the dean of automobile manufacturing and engineering, is making an automobile truck which has only about half the parts usually employed in these vehicles. Mr. Duryea's character is well known wherever automobiles are made or used, and purchasers or inquirers are sure to receive only the honest facts and to get whatever value Mr. Duryea says they will get. For informaton address the Duryea Laboratories, Philadelphia, Pa.

Nothing But Buick Sixes.

Two six-cylinder chassis, a small one and a large one, will constitute the line produced by the Buick Motor Co., Flint, Mich., for the coming season. The fours have been dropped. The small six will sell for $950 as a roadster; $985 as a five-passenger touring car; $1,350 as a three-passenger coupe, and $1,875 as a sedan. The larger chassis lists at $1,450 as a roadster, and $1,485 as a five or seven-passenger touring car. The smaller models are equipped with 3½x5 motors and 32x4-inch tires and the larger with 3¾x5 motor and 36x4½ tires.

Packard Much Reduced.

The prices of the 1916 Packard cars have been made public and show a reduction of from $1,150 to $1,800, as compared with the prices of the 1915 models. All open bodies of model I-25, or the small twelve, are listed at $2,600, which is the lowest price at which a Packard ever listed, and is $1,150 lower than the price of the 1915 3-38 runabout. Model I-35, which is the big twelve, is listed at $2,950 for all open bodies. This is $1,800 less than the price of the 1915 model 5-48 runabout, or big six.

Low Price New Era Cars.

The New Era Engineering Co., Joliet, sell a roadster at $600. The car has a 104-inch wheelbase and is fitted with a unit power plant consisting of a four-cylinder, L-head, block motor, four-speed gearset and dry-plate disk clutch. The axle is three-quarters floating. The motor is 3⅛x4½ and is said to develop 27 horsepower at 2,000 r. p. m. An Allis-Chalmers single unit cranking and lighting system is installed. Ignition is by the Atwater-Kent system.

Electrics Consolidate.

The Baker Motor Vehicle Co. and the Rauch & Lang Carriage Co. have merged into one company styled Baker R. & L. Co. For the purpose of merging the stock of the two companies the Rauch & Lang Co. will increase its present capital stock from $1,000,000 to $2,500,000, of which $750,000 will be 7 per cent. cumulative preferred and the remainder common.

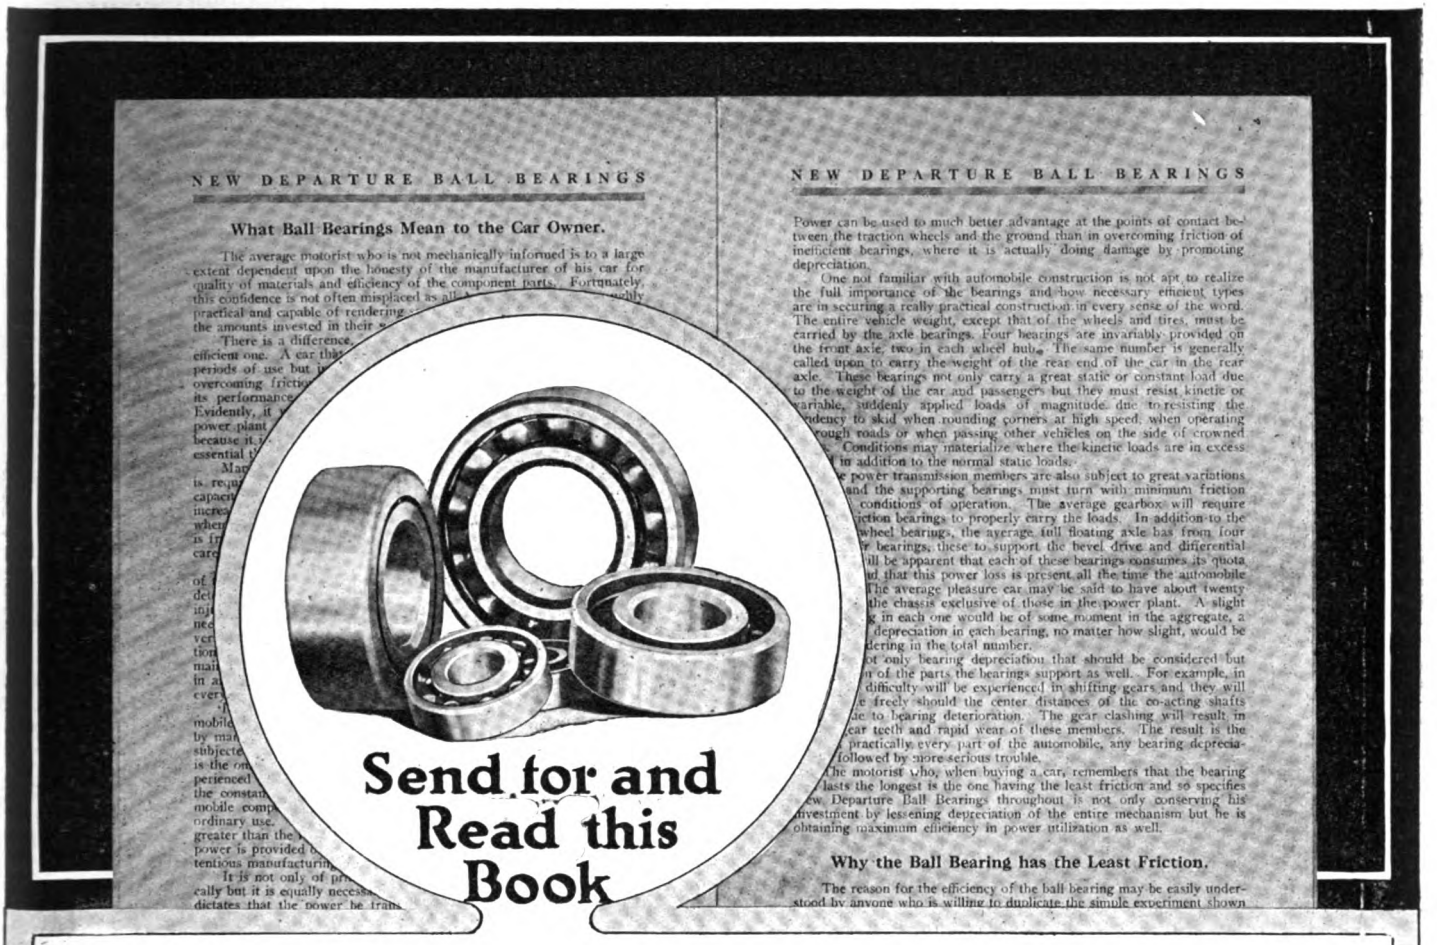
Free Chalmers Service.

The Chalmers Motor Co., Detroit, has made public the first details of what it styles a universal service plan which shortly is to be put in operation. The company will issue to each purchaser of a new car a book of labor coupons which will be negotiable, without cost to the owner, at any one of some 800 Chalmers service stations. The possession of a coupon book will entitle the holder to 100 hours of free service.

Suit Against Auto Parts Co.

Thomas F. Wilson, of Providence, R. I., doing business as the Auto Parts Company, has been made a defendant in an equity suit entered by the Ford Motor Company, in United States District Court. The defendant is charged with the unlawful and fraudulent use of the word "Ford" in the automobile business. A motion for a preliminary injunction restraining the defendant from using the word "Ford" was set down for a hearing on June 9, and an order issued to show cause why the prayer should not be granted. The declaration sets forth that the defendant conducts business in other States under the name of "The Illinois Ford Shop" in Illinois and the "The Wilson Ford Shop" in Pennsylvania; that they are not corporations, but mere trade names. It is further set forth that the defendant is engaged in the manufacture and sale of automobile parts in which the name of "Ford" is used unlawfully. The plaintiff asks "that the defendant be required to account to him for all profits and gains realized by him through his unlawful acts, and that the defendant, his agents and employes be restrained and enjoined from using the word 'Ford.'"

An Automobile College.



At 1519 Wabash Ave., Chicago, Ill., there is an automobile college which teaches the construction, repairing and driving of automobiles. It is stated that the graduates of this college are always in demand. It is called the Greer College of Motoring.

Trade Press Convention.

The tenth annual convention of the trade press of the country will be held at the Bellevue-Stratford Hotel, Philadelphia, September 7, 8 and 9, 1915. One of the purposes of this convention is to strike a keynote of co-operation in the interest of higher ethics, greater efficiency and larger growth. The Federation of Trade Press Associations is composed of 250 leading trade and technical journals and the attendance of this convention will no doubt be large. The chairman of the committee on arrangements is Bartley J. Doyle, and his address is 512 Race Street, Philadelphia, Pa.

NEW DEPARTURE BALL BEARINGS

American Made for American Trade

EXEMPLIFY true rolling motion—They are *not* point contact bearings.

In practical ball bearings there is no such thing as point contact.

In New Departure Ball Bearings there is always a well defined area of the balls under load, in contact with the raceways upon which they roll.

In rolling, the balls constantly present new areas of contact to the load. It is impossible therefore, for wear to concentrate upon any given area, as is always the case with all bearings other than the ball type.

A Genius and a Woman Suffragist.

Thomas A. Edison is one of the best friends the woman suffrage cause has. He not only advocates it by spoken and written testimony, but has declared his desire and intention to lend his genius to forwarding the cause in some concrete way a little later in the campaign.

Warm Gasoline.

Of course, warm gasoline will evaporate into a good explosive mixture quicker and better than cold gasoline. It is a good plan to run the feed pipe which goes to the carburetor alongside of the exhaust pipe, fastening it there with wire.

Circuit-Breaking.

In the make and break of current of a magneto the space between the contact points is very important. If the space is too wide the engine will tend to miss at slow speed, and if too close it will miss at high speed.

Speed on Low Gear.

Anxiety to go faster when running on low gear is responsible for very many of the breaks in transmission, universal joints, differential and driving axles.

When the grease works endways through the axle housing and comes out in the brake drum it is because the big felt washer has become inefficient. A new one may be easily made from the felt collar pads to be found in any harness shop.

HOW TO BUY ADVERTISING

Buy it exactly as you would dry goods or groceries.

Be sure you get the quantity and quality you bargain for and at a fair market price.

To determine the good weight or measure, see that the publisher belongs to THE AUDIT BUREAU OF CIRCULATIONS. This ensures the quantity.

To determine the quality, find out who are the readers. If you want to reach automobile owners, garages or repairmen, do not advertise in mediums of general circulation, for this will be a shoddy quality—possibly 10 or 15 per cent. good. To be certain the medium is "all wool and a yard wide," choose one that reaches no other readers except those you want to reach; this means 100 per cent. good.

Finally, find out the market rates for advertising of the quality and quantity you are about to purchase—and pay no more.

If you purchase your advertising in this practical, business-like and fair way, you may be sure it will pay you, provided you have something to sell that those want to whom you appeal.

Another New Car.

New York and Akron interests are behind a plant to manufacture a four-cylinder, five-passenger touring car and roadster chassis to sell, with complete equipment, at $980 to $990. A feature of this car will be the careful attention to blending of lines of the body, cowl, hood and radiator, while several novel ideas are included. The touring car is to be five-passenger with divided front seats and the roadster carries three in clover-leaf fashion. The whole car will have a low appearance due to the front axle being dropped. The doors, instead of being vertical, will be raked to harmonize with the general design. The radiator will have a tall, narrow appearance when viewed from the front and no dash lights will be employed. The block motor will be 3¾ by 5½, giving an S. A. E. rating of 22.5 horsepower. The water is circulated by a pump. The lubricating system is a circulating splash. Ignition is by magneto, and electric lighting and starting are furnished.

Firm Changes Name.

The Garage Equipment Manufacturing have changed the firm name to the Gemco Manufacturing Company, of Milwaukee. Its well established trade mark distinctly identifies the firm and what it stands for. Service, co-operation and quality of merchandise have been the main factors in the success of this company. To-day the Gemco Manufacturing Company have the distinction of being the largest general manufacturers of automobile accessories in the world. There are at the present time considerably over two hundred articles in the extensive line consisting of standard automobile accessories and Ford specialties.

The New Gasoline Process.

Secretary Lane has announced that excellent progress was being made in the development of the gasoline and benzol processes designed by Dr. W. F. Rittman, of the Bureau of Mines, to increase the output of gasoline by refiners and to make possible the production from crude petroleum of toluol and benzol, which are the bases for dyes and high explosives. The gasoline process is now ready for large-scale industrial application. The benzol process is being developed in co-operation with the Aetna Chemical Co., of New York, which company has entered into an agreement whereby all patentable equipment, processes and ideas available will be turned over to the department to be dedicated to the public. The department stands ready to enter into similar agreements with other companies.

Ford Parts Prices.

The Ford Motor Co. has revised the prices of all parts for Ford cars. Practically all of the 600 items on the parts lists shows a reduction of from 10 to 25 per cent. There are, however, a few parts which now cost more, the manufacturing cost at present being higher than formerly. For instance, front axle assembly now is listed at $24, instead of $22; rear axle assembly at $55, instead of $60; fenders, at $2.50, instead of $3; coils, now $16.50 instead of $18; radiators, now $15 instead of $20.

Convict Labor for Massachusetts Roads.

Massachusetts has just passed an act providing for the improvement and repair of highways by convict labor. The act provides in addition that convicts may be used by owners of waste land for its improvement. The national committee on prisons and prison labor, while sanctioning the road work section of the act, condemns the part relating to contract labor being done by convicts. It is expected that at the next session of the legislature contract convict labor will be abolished in that State.

For the Water Jackets.

Young's radiator compound is said to be an excellent one for cleaning water jackets. It is guaranteed to be harmless and is said to absolve all scale, rust and metal deposits. It is made by H. E. Ketchum, 11 Thirteenth St., Whitestone, N. Y.

RALPH N. FLINT, M. E.—Attorney-at-law in Patent Causes, late Assistant Examiner Internal Combustion Engine Division, U. S. Patent Office. Specialist in Internal Combustion Engine Cases. 2 Rector Street, New York, N. Y.

Chevrolet Prices Reduced.

The Chevrolet Motor Co. has made a material reduction in the prices of the Baby Grand, which is a five-passenger car, and the Royal Mail, a roadster. The touring car has been reduced from $985 with full electrical equipment to $750, a difference of $235, and the roadster from $860 to $720, a difference of $140, also including electrical equipment. The five-passenger 4-90 sells at $490 without electric lighting and starting and $550 with it.

Ford Reduces Prices of Parts.

The Ford Motor Co. has made a reduction on most of its parts, ranging from 10 to 25 per cent. A few parts, however, which it was found cost more to manufacture now than heretofore, were increased in price. For instance, the front axle assembly now costs $24 instead of $22. On the other hand the rear axle assembly, which formerly listed at $60 now costs $55. Radiators have been reduced from $20 to $15; fenders from $3 to $2.50.

Money in Racing.

The opening of the new two-mile Sheepshead Bay Speedway, New York, will without doubt take place Saturday, October 2. Instead of ten money prizes, as given at Indianapolis, there will be twelve, with $20,000 to the winner, $10,000 to second, $6,000 to third, $3,000 to fourth and $2,500 to fifth. The last seven prizes are $1,600, $1,400, $1,300, $1,200, $1,100, $1,000 and $900. Entries will close September 1 the fee being $200 per car, which is returned if the car starts.

White Tank Trucks for Russia.

The White Co., of Cleveland, Ohio, has received an order for 300 tank motor trucks for the Russian army to be used as tenders for the thousands of motor cars and trucks at the front. The order will amount to about $1,000,000. The White Co. recently completed a large order of similar trucks for the French army. The plant is now being operated with three shifts.

Sheldon Increases Output of Gears.

An increase of 43 per cent. during the fiscal year ending September, as compared with the previous period, was shown in the worm gear truck axle department of the Sheldon Axle and Spring Co., Wilkes-Barre, Pa. Since that time production in this department has continued to increase, the seven months of the current fiscal year showing an increase of 42 per cent. over the corresponding period of the previous fiscal year.

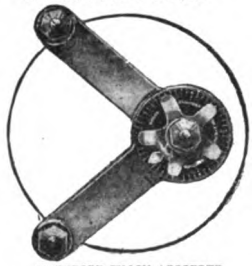
MORE COMFORT GREATER SAFETY LESS EXPENSE

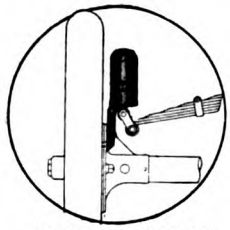
WHEN YOU USE STANDARD Hartford EQUIPMENT FOR Ford CARS

Standard Hartford Equipment increases the pleasure of Ford ownership by contributing to more comfort, greater safety, less expense.



Here is a Comfort Combination

that will make a Ford ride with marvelous smoothness over **all** roads, and incidentally cut upkeep expense. It is the result of long, careful study of Ford requirements, supplemented by severe road tests. Here it is:—



FAMOUS *Hartford SHOCK ABSORBER
On the front of a Ford

AND

FAMOUS Hartford CUSHION SPRING
On the rear of a Ford

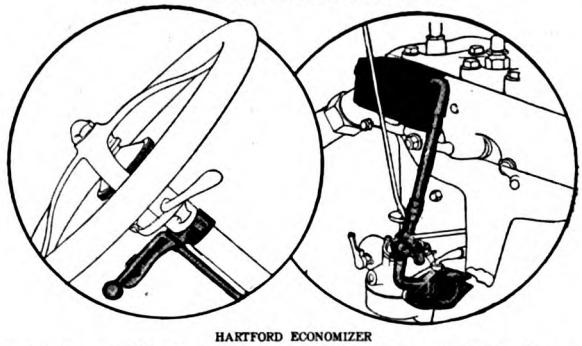
HARTFORD SHOCK ABSORBER

HARTFORD CUSHION SPRING

You have noticed that it is more comfortable to ride in the front seat of a Ford; this because the weight of the engine has a steadying influence on the front part of the car. The presence of a Hartford Shock Absorber, here, has the effect of accentuating this steadiness when rough roads are encountered, preventing, as it does, the violent spring action which would otherwise occur because of the extra weight at this point.

Since there is less weight at the rear, there is necessarily limited spring action. Greater resiliency is desirable here. Two Ford type Hartford Cushion Springs supply it.

This Hartford combination solves the problem of solid auto comfort for Ford owners. You can test it and satisfy yourself of its effectiveness, with the guarantee—"Money Back if Not Satisfactory."



PRICE One Hartford Shock Absorber, Ford Type / Two Hartford Cushion Springs, Ford Type **$12.00**

Get 35% More Mileage

Every gallon of gasoline can carry a Ford over one-third farther than it now does. While doing this, its owner can enjoy more power and a smoother running engine. Can decrease carbon deposits. These advantages are positively realized as soon as a Ford is equipped with the

* Formerly Truffault-Hartford.

Hartford ECONOMIZER

HARTFORD ECONOMIZER

designed especially for Ford cars. It furnishes an ideal mixture. Utilizes more air and less "gas." Feeds the engine the most effective kind of fuel. Try it. You will quickly recognize its great economic value. It must make good—"Money Back if not Satisfactory." Easy to put on by anybody.

PRICE, with fittings complete, $6.00

Gives a Ford a "Classy" Look

while protecting its fore parts from collisions—a

Hartford Bumper

HARTFORD BUMPER

Ordinary collisions then prove harmless to lamps, radiator and mud-guards; severe collisions cannot damage the car itself, because the two arms of the Hartford Bumper are real shock absorbers. They dissipate the force of heavy blows, thus protecting **all** the car. Light in weight; trim in design; tremendous in strength; practically indestructible. Gives the effect of longer lines to frame and car; adds greatly to its appearance. Designed especially for the Ford. Easily put on in 15 minutes. Saves its purchase price many times over during the car's life.

PRICE COMPLETE, $10.00

Complete descriptive matter on all Standard Hartford Equipment for the Ford, on request. A Liberal Sales Proposition for Dealers. GET IT.

5
Extra Horse Power

Every Ford owner can add 5 Horse Power to the actual working efficiency of his motor. We guarantee it and prove it on your car at our risk. It costs you nothing to prove our claim. Replace your carburetor with a *Brad-Kent* and see how much more easily you can drive up steep hills or through deep roads. Note how much more quickly you can get away from a standstill.

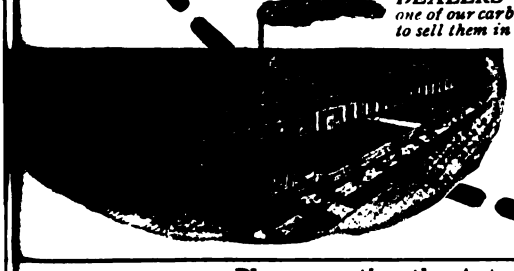
New Ford Model

Brad-Kent  Carburetor

Patents Allowed

The *Brad-Kent* carburetor is constructed upon a new scientific principle. It is the only efficient carburetor with but a single adjustment. Mixture is always the same, regardless of speed. Works as smoothly at 4 miles per hour as at 35 miles.
Lighter, simpler and more easily handled than other types. Easiest to start in cold weather. No water jacket to freeze. Gas and air both regulated by speed of the motor. Cylinders fill better and the perfect mixture will not deposit carbon. The price for the complete Ford outfit is $15.00—money back if not satisfied in 30 days. Try it on your own car. Make us prove our startling claims.

10 Miles Extra Speed



Put a *Brad-Kent* on your car today. And tomorrow you can drive 10 miles faster—on less gasoline consumption. We guarantee to beat other carburetors by at least 10 miles. Make us prove it.

Saves 2 Gallons Out of 5

The *Brad-Kent* will carry you 32 miles on the same amount of gasoline you now require for 20 miles. We have proved this many times. We are so sure of this that we guarantee to drive your car as far and as fast on 3 gallons of gasoline as you can now travel on 5 gallons. In a recent official test conducted by F. E. Edwards, Official Observer for the Chicago Automobile Club, a Model "T" Ford was driven at an average of 33.12 miles per gallon. This record was made in a run of 102.1 miles between Chicago and Milwaukee. You want this extra horsepower. You will enjoy this extra flexibility and speed. You need this marked saving in gasoline consumption. And we positively guarantee to you *all these things*. Our responsibility is well known. Make us show you.

30 DAYS' FREE TRIAL Mail the attached coupon with Check or Money Order for $15.00. We will promptly send you a *Brad-Kent* Carburetor, manifold, hot air tube and stove. Install it on your Ford. It can be done in a few minutes without special tools. Then try it for 30 days at our risk. If you are not satisfied in every way just send the outfit back to us and we will promptly refund your $15.00 in full. No questions asked. Your money back, regardless of the reason why. You are the sole judge.

DEALERS—Be sure to write for our attractive dealer proposition. Try one of our carburetors and see how much better it is. We will help you to sell them in your neighborhood. Write today.

Little Giant AUTOMOBILE SCREW PLATES

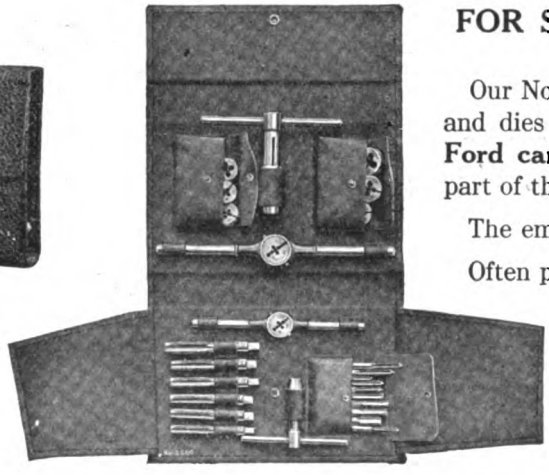
GOOD WORK REQUIRES GOOD TOOLS

Now that the overhauling season is at full blast repairmen and garage owners need tools for cutting screw threads by hand and should have the best. Out of our large and varied list of assortments of taps and dies we want particularly to call your attention to the screw plates, one of which is illustrated above, called

Little Giant COMBINATION ASSORTMENTS (Containing both S. A. E. and United States Standard Threads.)

These assortments avoid the expense of buying a separate outfit for each thread standard and the expense of duplication of stocks and tap wrenches.

Little Giant DIES CUT EASIER **Little Giant DIES ARE MORE DURABLE**



Impossible for them to tilt or get out of alignment. Increasing the working strain only tightens the grip of the collect upon the working parts of the dies. Send for circular, "Tools for the Automobile." A postal brings it.

WELLS BROTHERS COMPANY DIVISION

LIGHTNING EMERGENCY REPAIR KIT

FOR SCREW THREADS

Our No. 2500 assortment of taps and dies is designed especially for **Ford cars,** is equally useful as a part of the equipment of any car.

The embodiment of utility.

Often pays for itself on one job.

Genuine Goat Skin
Leather, Canvas Lined
Hardwood Case
if desired

LIGHT, COMPACT
DURABLE
CONVENIENT

Has 16 taps, 16 dies, 2 stocks and 2 tap wrenches

Dealers will find a great demand for these sets and we are looking for live agents in every territory to handle them. Write for proposition today.

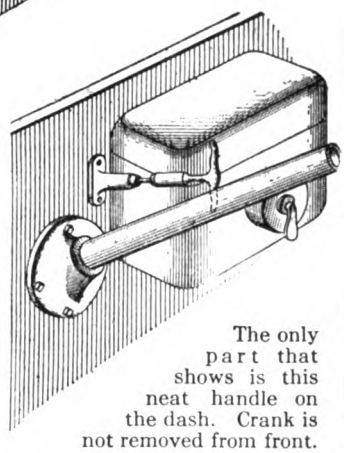
$10

Think of it!

A SELF STARTER FOR 10 DOLLARS

The HUNTER



Complete with all attachments and instructions

JUST WHAT THE FORD OWNER HAS BEEN LOOKING FOR

At Last Mr. Ford Owner!

Your wish has come true. The best starter for a Ford car ever devised and costs less money. It gives you every convenience of the bigger, costlier cars (as you can use electric headlights on your magneto current).

INSTALLED IN ONE HOUR BY ANYONE

The only part that shows is this neat handle on the dash. Crank is not removed from front.

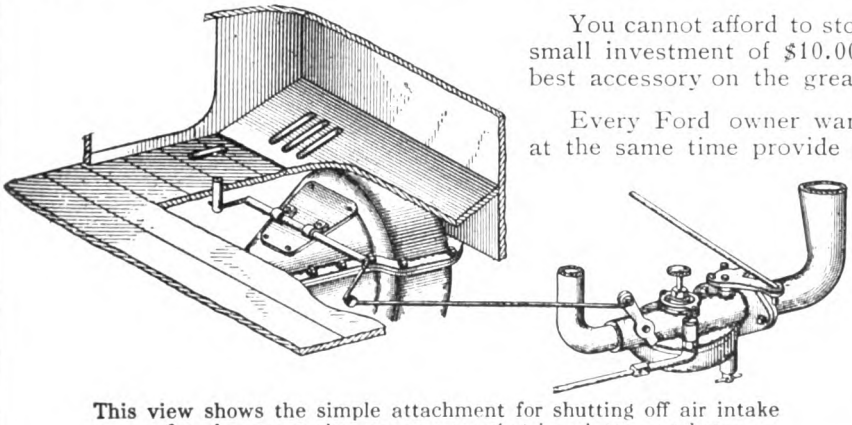
INCREASES THE VALUE OF A FORD THREE TIMES

Note the Advantages

Powerful—The straight pull and powerful leverage enable a woman or girl to start it.

Simple—Installed in one hour. Nothing to get out of order.

Inexpensive—Costs little. No operating or installation expense.



Convenient—Easier to start motor from seat than from the crank.

Reliable—Entirely mechanical—can't fail to turn motor. Special attachment to close air intake of carburetor for easy starting in winter weather.

Appearance—Handle on dash all that shows. Crank not removed from front.

You cannot afford to stop at the small investment of $10.00 for the best accessory on the greatest automobile on the market.

Every Ford owner wants to make his car up-to-date and at the same time provide for comfort.

This view shows the simple attachment for shutting off air intake of carburetor to insure easy starting in winter weather.

FORD OWNERS:—Write today for full description, or order through your dealer or direct from us.

DEALERS:—Don't fail to get our proposition at once. Big money for you in this—the lowest priced reliable Ford Starter made.

HUNTER LOCKS for FORD CARS:—A simple bracket and lock attached to steering column, making it impossible to steer car when locked. Price, $1.00. Quickly installed. Sold by leading dealers.

THE HUNTER AUTO SUPPLY CO.

4101-5 EAST RAVENSWOOD AVENUE CHICAGO, ILL.

Digitized by Google

UTILITY

PRICE $10.00
Complete with
Pneu-Meter

THE ONLY TRULY AUTOMATIC TIRE PUMP ON THE MARKET

The Pneu-Meter installed on the hose line prevents over inflation as well as under inflation. Connect your pump, set your Pneu-Meter at the right pressure, start your engine and forget it.

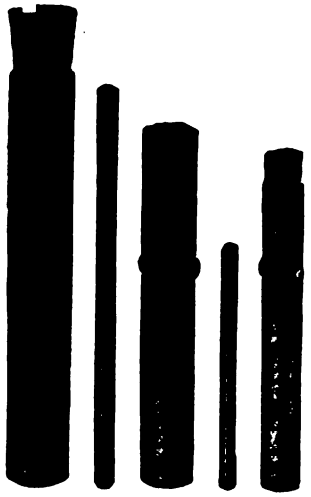
You don't have to watch your pump—the Pneu-Meter does it for you—when your tire is properly inflated, it becomes a **Safety** blow-off valve, using excess pressure to sound a continuous signal. **So simple a woman can work it.**

PRICE $2.00

UTILITY Jr.

PRICE $6.00
Complete with
Pneu-Meter

WHISTLING PNEU-METER



Sold separately and can be installed on the hose line of any other spark plug or gear driven pumps, garage air tanks, etc.

Absolutely accurate and cannot get out of order. Whistles loudly and can be heard fully a block away, and will continue until the engine stops.

Over and under inflation decreases the life of your tires. This is due to the use of tire pumps which are equipped with ordinary dial gauges and which at the best are inaccurate. This trouble and expense can be absolutely avoided by using **Utility Pumps equipped with Whistling Pneu-Meters.**

Smallest and fastest—simplest and best constructed pumps ever made—**absolutely safe.**

Built of rust-proof bronze, brass and nickeled steel. **LASTS A LIFETIME.**

7', 6' and 5' Long Respectively

The UTILITY Socket Wrench Set

A New Principle With Many Advantages

Has all the advantages of socket wrench sets consisting of fourteen wrenches, with none of their faults. Instant in adjustment. No screws to manipulate, or parts to get out of order. Can be applied to all shapes and kinds of nuts, immediately. Has many new features possessed by no other wrench.

SOME NEW FEATURES

Will grasp any nut instantly and requires no further effort to hold wrench in place. In removing, the jaws hold nut firmly at all times, so it cannot fall or become lost. On the other hand, nut can be placed in jaws and applied to bolt or screw when same is inaccessible to the hands.

Unequalled for use in Garages and Machine Shops, in fact, wherever nuts and bolts are used.

Will take all nuts from ⅛ to ½ inch, inclusive.

Will take all nuts used in auto work.

Will take hexagon nuts, square nuts, wing nuts, cock nuts, and nuts rounded or distorted by use of other wrenches.

Cannot slip and bruise fingers of workmen, as jaws have rigid bearing on four sides—the harder you pull, the harder the jaws grab the nut.

Look at its wonderful advantages and then look at the price.

Utility Wrench Set Complete, $2.50

Packed in neat canvas bag.

Write for Our Dealers' Proposition.

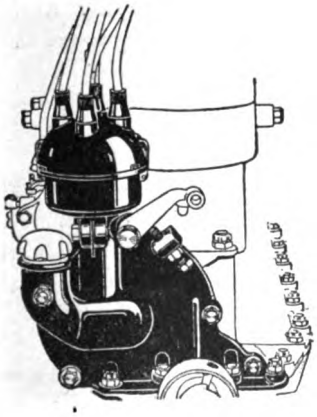
For your **FORD**

Atwater Kent Ignition

Your first ride in an Atwater Kent-equipped Ford will surprise you—you will see for yourself the wonderful performance of this remarkable motor when equipped with the same modern high-grade ignition system which has displaced the magneto on thirty representative American cars.

Imagine running through a crowded street at three or four miles per hour on high, and, at the first break in traffic, accelerating with all the smoothness and rapidity of a "light six" up to the limit of your speed, without changing gears or touching the spark lever.



Just think of a scientific ignition system which gives you a single hot spark, uniformly hot and exactly alike in each cylinder, no matter whether the motor is being cranked slowly or is running at forty-five miles an hour—and at the same time ridding your dash of the noisy vibrating coils with their fussy and delicate adjustments.

The wonderful automatic spark advance which is only one feature of the Atwater Kent System, makes the motor self-regulating. The spark is always safely retarded for easy starting, automatically advanced for high speeds and automatically retarded for low speeds and hill climbing. The driver can forget the spark lever and control his car by means of the throttle alone, leaving both mind and hands free.

In installing Atwater Kent Ignition you join a mighty army of two hundred thousand owners, ten thousand dealers, two hundred jobbers, and thirty manufacturers, all of whom can certify to its success. More than one-quarter of all the cars made this year, exclusive of Fords, are Atwater Kent-equipped.

MAGNETO REPLACEMENT — For cars of all makes we furnish the Atwater Kent System, mounted on a universal base so that it may be easily installed in place of any standard magneto at reasonable cost.

The car owner who has put up with the limitation of magneto ignition can not only improve the starting and slow speed qualities of his car, but can enjoy all the advantages of automatic spark control, flexibility and better acceleration, now being experienced by thousands of other enthusiastic Atwater Kent users.

When your car is Atwater Kent-equipped you have the satisfaction of knowing that money can buy no better ignition equipment and that your judgment is upheld by a large number of the foremost automobile engineers in the country.

DEALERS, GARAGE AND REPAIRMEN

Thousands of them recommend Atwater Kent Ignition because it "stays sold"—there is no question of a come-back. The user is enthusiastic and brings them other customers.

Write for dealer's data.

FREE: **Write your name and address NOW on the margin of this advertisement, or send a postal for an interesting Ford story, "Why Smith Kept His Ford," together with complete descriptive matter relative to this famous ignition system.**

Jumbo Spark Plugs

(Red Elefant Brand)

are right husky fellows
that take their daily punishment
without a whimper.

The Jumbo Jiant is a heavy duty plug. Behaves beautifully under all sorts of conditions. Note its sturdy construction.

Guaranteed for One Year

You will make a hit with your trade by stocking Jumbo Plugs. Your customers will say: "Bully good plugs; give me a spare set."

Made in ⅞ A. L. A. M., ½ inch Metric and special Buick sizes. Retails $1.

—no other plug will satisfy your customers like the Jumbo. Here are a few reasons why—

Steel Shells

The shells of Jumbo plugs are cold rolled steel. Better than brass—greater tensile strength. And practically no expansion under heat.

Won't Rust

To overcome rusting, we employ a new metal finish which is an absolute preventative of rust. It withstands 1,200 degrees F.

Extra Strong Porcelain

Practically impossible to break or crack the porcelain except by a hard blow. By building the porcelain on the top instead of the lower shoulder, it gives twice the distance for expansion and contraction. Thus it reduces the danger of cracking or breaking as a result of heat.

Scat to Soot!

The porcelain skirt is so arranged that each explosion blows the end free from soot. And notice how the shell electrodes are bent in the middle. They lead the oil ***away*** from the firing points.

List prices range from $125 to $75. Fits Ford or other chassis

Ford Dealers—Here's the New Beverly-Cotton Body

Isn't it a beauty? Ever seen anything half as classy? It's a real aristocrat. Style sticks out in every line of it.

Sells At Sight

Man alive, how this Beverly-Cotton body will sell! Right now while you're reading this you can think of at least half a dozen Ford owners you can land. They'll jump at it. Just show them the illustration. And then hear them say: "Get me one—quick!"

Big Profit For You

And listen—Every Beverly-Cotton body you sell means a nice, juicy profit. The finest way of fattening your bank account just now is to sell Beverly-Cotton bodies. Just like picking cherries.

Cotton Is King

of the automobile body business to-day. You've heard of Cotton. He's had the most phenomenal success of any man in the automobile business of New England. He's *Ford* when it comes to automobile bodies—don't mistake that. You're a Ford agent—be a Cotton agent also. You'll make oodles and oodles of coin—as Cotton has.

You just "cotton up to Cotton" and you'll be a winner.

An Every-Purpose Body

This Beverly-Cotton model is an every-purpose body—that's the beauty of it. Makes a fine club or private omnibus for theatre or station use. Take out rear seat and you have a dandy delivery body.

Honest All Through

Wish you could see this Beverly-Cotton body without paint or varnish. We wouldn't need, then, to say another word. You'd see for yourself the quality materials, the quality workmanship—and that would settle it. You'd buy nothing but Cotton-built bodies ever after.

The Inside Story

But since you can't come to the Cotton factory, let's give you the inside information here. First of all, the Beverly-Cotton is built by carriage builders at Amesbury, Mass. The town's known the world over as carriage center.

Well matured oak and ash—nothing else is used, except in the top, which is of whitewood to make it light. We use the most expensive roofing material. Storm curtains are the best oiled duck. Cushions are of box construction with curled hair and steel springs. Cheaper stuff would look just as well, you know. We have crowded 100% more quality into this body than anybody else would dare to do. And in spite of that, the price is mighty low. You'll never hear of anybody else building a body like this for anywhere near the price.

ASK YOURSELF THIS:

Are you taking big losses on your "swap" stuff—or scrapping your old chasses? Here's what you do—put Cotton-built bodies on them and your hard-to-sell cars. You'll get good prices and make big profits. We carry more than 50 models in stock, most of them our own make. Anywhere from 350 to 400 bodies—all colors—always on hand. And cheap! cheap! Quick shipments. Write today—now—while it's fresh in your mind.

ROMORT AIR NOZZLE---CUSHION CLEANER

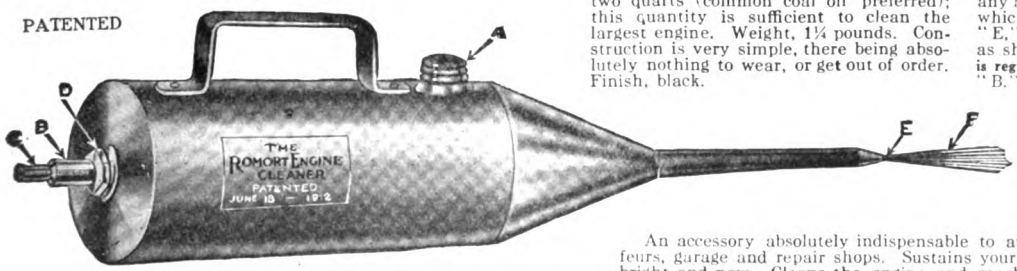
Price 25 Cents Each

The handiest little device ever invented for the purpose of **blowing the dirt and dust off cushion tops, foot mats, machinery, etc.** When attached to a Romort Automatic Air Valve, or Pump Connection, air flows out of the needle point **with terrific force**, forming a perfect and effective Air Cleaner. Ask your Dealer, or order direct.

ROMORT PUMP CONNECTION RUBBER---or ROMORT RUBBER WASHER

FITS ALL VALVES AND PUMP CONNECTIONS

One Dozen Rubbers to a Carton **Price 25 Cents per Carton**



A scientific Romort design, made of a Special Compound of Rubber (not dope), has the best wearing qualities. Easily slips on the tire valve, **Will hold fast and will not turn inside out. Don't be misled by cheap inferior washers similar to Romort design—Genuine Romort Rubbers are stamped "Romort."** Leading Jobbers and dealers carry **Romort Rubbers** in stock—if yours don't, fill out Coupon below.

The Romort Engine Cleaner

PRICE $3.00 Each

PATENTED

DESCRIPTION

The Romort Engine Cleaner is 20½ inches long by 4 inches in diameter, a convenient size for carrying in a car. Fluid capacity, two quarts (common coal oil preferred); this quantity is sufficient to clean the largest engine. Weight, 1¼ pounds. Construction is very simple, there being absolutely nothing to wear, or get out of order. Finish, black.

HOW TO OPERATE

Fill the tank as shown in the cut at letter "A," attach the cleaner to hose or air supply at letter "C," (standard connection will fit any air hose). Turn knurled rod at letter "B," which opens valve and lets fluid out at letter "E," fluid is forced out in a very strong spray, as shown by letter "F." **Light or heavy spray is regulated** by a slight turning of knurled rod "B." The packing nut, as designated by letter "D," may be easily detached and repacked if found necessary.

NO DANGER OF EXPLODING

As the air does not enter the tank, but passes right through, picking up the fluid at letter "E," there is absolutely no danger of the tank blowing up—this being impossible.

An accessory absolutely indispensable to automobile and motorcycle owners, chauffeurs, garage and repair shops. Sustains your car efficiency by keeping the machinery bright and new. Cleans the engine and machinery perfectly without the use of rags, **waste or brush. Designed for the special purpose of cleaning automobile and motorcycle engines and machinery, it is constructed with a long spout or point, so the operator may easily reach every nook and part of the machinery, an impossibility with the old method of rags and waste. The dirt and grease readily disappear before a strong spray, which works under a very low air pressure. Use an engine-driven or spark plug pump, garage storage systems or in fact any air pressure system from 10 pounds to 200 pounds. It cleans the machinery of your automobile or motorcycle just as readily and with the same result as one would hose off the outside of the car. The Romort Engine Cleaner, one quart of coal oil and five minutes of your time will do the work.**

For sale by all up to the minute Dealers or order direct - See Coupon attached.

ROMORT MANUFACTURING CO., Mfrs. of Romort Guaranteed Specialties, **1322-1326 Michigan Ave., Chicago, Ill., and 1810 Westlake Ave., Seattle, Wash.**

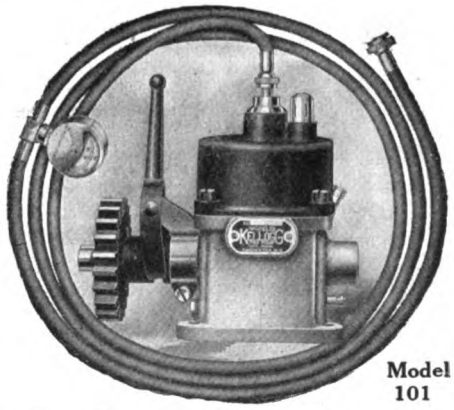
"Never Again"

Every Car in Your Locality Needs a Good Engine-Driven Tire Pump



Do you appreciate the profit you could make by selling the Kellogg?

Not one model pump for all cars because that is impossible. We have six years' experience making pumps **with carefully designed attachments** so that in spite of cheap competition there are more Kellogg pumps in use today than all other makes combined.

Engine Driven KELLOGG Tire Pump

Study this list of cars—make the most of your opportunity. The Kellogg pump will be furnished for 1916 as follows:

For 1916 Cars Kellogg Pumps are		Thousands sold with attachments to dealers for
Regular Equipment on	Special Equipment on	
Franklin	Buick	Buick
King	Chalmers	Dodge
Lexington	Chandler	Ford
Peerless	Fiat	Hudson
Premier	Hupp	Overland
Simplex	King	Reo
Stewart	Mitchell	Studebaker
Velie	Stearns	and many others
	Westcott	

Model 101

The Perfect Pump With Perfect Attachments

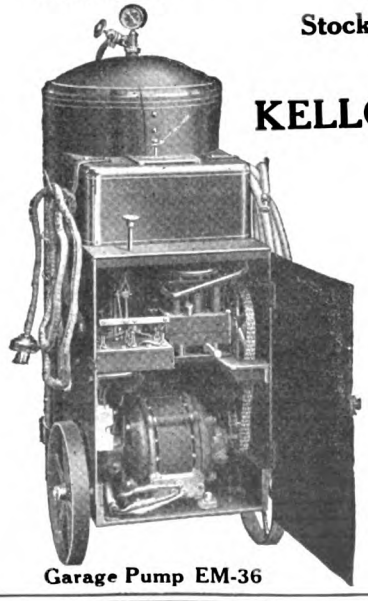
"Guaranteed not to spray oil with the air."

There is no need for you to furnish makeshift outfits made to meet a demand when Kellogg Tire Pumps are made in different models to meet special requirements of different cars.

Model 101 With Complete Attachments $15 Special Dodge Outfit $10 Special Ford Outfit $9.50

All Kellogg pumps are made with metal piston rings—grey iron cylinders and air supplied with poppet valves, both intake and exhaust (ball check valves always leak and heat the air), as well as other features which make for its superiority.

Attachments Designed for Each Car make Installations Easy—Without Machine Work.



Prompt Delivery from Stock Carried by Distributors and Service Stations as follows:

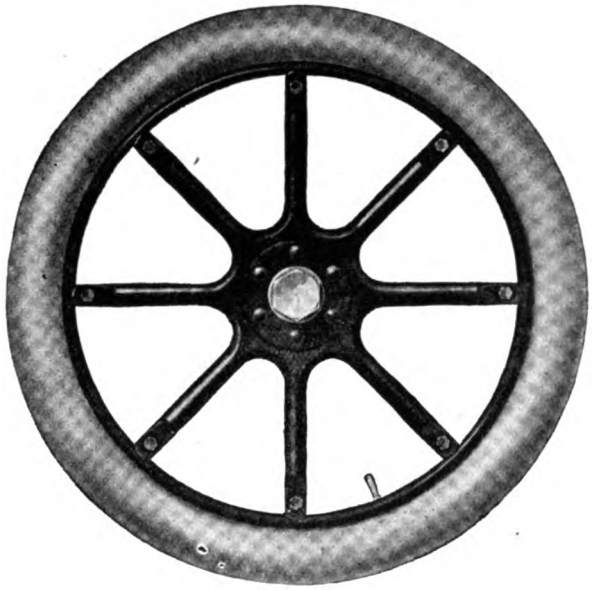
Garage Pump EM-36

For Your Own Garage Use



We make several different styles of portable and stationary outfits. The one illustrated takes air to the cars. Saves one-third to one-half on power bills.

Just as car manufacturers found that we could make a better engine-driven tire pump than they could make themselves or buy anywhere, so you will find that we can furnish you with a garage pump outfit better than any makeshift device you can secure. Our whole business energy is given to making tire pumps.

Ask your nearest distributor or write us direct in regard to your requirements.

PARKER-HYDRAULIC
PRESSED STEEL WHEELS For Ford Cars

STRONGER than WOOD or WIRE WHEELS

CHANGE TIRES and be running again IN TWO MINUTES

Forty pounds lighter per set than wood wheels with demountable rims
Carry your spare tire inflated on extra rim which we furnish

Note these facts: You get—

1. More mileage due to less weight and ability of steel to conduct heat from tires.
2. Quicker acceleration on account of the lighter unspring weight.
3. Greater mileage per gallon of gasoline.
4. Greater durability. Steel will not dry out like wood or break like wire.
5. Better appearance. Enamel is baked. It retains its lustre and does not crack off like paint.
6. Prompt service in mounting Parker-Hydraulic wheels. They can be put on at your garage in two hours.
7. Every advantage of wood and wire wheels with all disadvantages eliminated.

OPERATION

To remove the rim: unscrew each bolt about three turns. The loosened clips may then be turned to release the rim. To put on new rim with tire: set rim on spokes having the upper position with valve stem between any two spokes and the rim will swing into position.

Write for prices and full particulars

TEMCO Automobile and Garage Necessities

TEMCO Shock Absorber For FORD Cars

They take **all the** slight jars which your big springs would pass along to you.

They catch the first shock of all big jars and hand the load to the springs gradually.

They take the rebound from the springs gradually—and you are saved from all sudden or violent jars and jounces.

3 Big Features

Combined In No Other Ford Shock Absorber

1 Telescoping Dust Cap

The fender rods on Ford cars would ordinarily strike the top of a shock absorber as tall as the Temco. But Temcos **telescope** and "duck" the blow.

So we don't have to make them lean over to avoid the fender rod.

Temcos stand erect as sentries and add to the appearance of your car. They are absolutely vertical.

2 Longer Springs Stronger Springs

Even when telescoped, Temcos are as tall as others. When normal, they are the **tallest.** This is a big advantage.

It lets us use **longer** springs.

And we make them **stronger** and more **flexible** too. We use **two** Genuine, Crucible, **Vanadium,** Helical Steel Springs in each shock absorber.

They **couldn't** be longer — they **couldn't** be stronger.

3 Radius Links To Prevent side-Sway

Temco Shock Absorbers never lean one way or the other. They stand uncompromisingly erect—always absolutely vertical—giving full spring action.

Radius Links **hold** them straight.

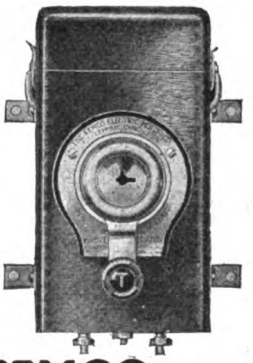
This prevents that tiring side-sway.

And side-sway is the beginning of the dangerous skid.

By preventing side-sway, Temcos minimize skidding.

$15 Complete Set of 4

Unlimited Guarantee



Temco Shock Absorbers must fully, thoroughly and completely satisfy you in every way, or you may return them and get your money back.

To Dealers We were the first to make shock absorbers for Ford Cars and we've made and sold thousands more than anyone else. We are right behind them as we have been for years. We've a valuable reputation to defend. When you stock Temcos you stock the shock absorber which already stands highest in the confidence of most Ford owners and the one which will make a trade-boosting friend every time. Write for any information you desire.

10,000 MILES GUARANTEE BACKS THIS TIRE

TRY Brictson Pneumatic Tires at our expense. Don't pay until you are satisfied. At our risk find out for yourself what wonderful service Brictson Tires give—how resilient and easy riding they are. Get rid of punctures, blowouts and rim cuts. Brictson Tires are rut proof, oil proof and gasoline proof. They are sold under a specific 10,000 mile written service guarantee.

Read What One User Says

"Several months before beginning my trip from Detroit, Mich., to Detroit, Fla., I thoroughly investigated tires of several well advertised kinds. I finally decided for my trip that the Brictson was the most economical and durable tire that I could find.

I am daily asked if I have many punctures. I reply that I do not know what a puncture is. I am driving on all kinds of roads under all kinds of conditions and never have a thing to worry about.

I have been on the road since the 8th day of last October, and if all goes well will begin my Florida trip again about October 1st next. I consider the tires worth almost their weight in gold. I would not do without them at twice the price.

W. J. BREWSTER,
August 10, 1914. 236 Jefferson Avenue, Detroit, Mich."

Your Tires Rebuilt the Brictson Way

If the fabric in the tires you are now using is in good condition, we can take them, make them proof against rim-cutting, punctures, blowouts, side-wall breaks, skidding, ruts, oil, and give thousands of miles of additional service.

Sign and send back coupon for full information and details of our liberal Free Trial Plan.

"Of Course A Tire-Doh Repair Is Permanent, Dad— It's Tougher Than the Tube Itself."

There is no use trying to make puncture or blow-out repairs that are likely to burn up the tube, or come loose under extreme temperature.

If you want to take all the after-worries out of your tire repairing, use

TIRE-DOH

Anyone who can drive a car can make a repair with Tire-Doh and do it easily, whether the hole is a pin-point puncture, or a tear a yard long. And when you have made a repair with Tire-Doh, you can be sure it will last, for

Tire-Doh Repairs Are Permanent Repairs

Tire-Doh is made by a secret process of the best rubber, and after it sets is tougher and more elastic than the tube itself.

No heat—no tools necessary to make a repair with Tire-Doh. You can use it anywhere—on the road, in the garage, and 2 cents worth of Tire-Doh will repair the average puncture.

Because of its plasticity, Tire-Doh can be used to make repairs such as reseating valve stems on inner-tubes that are impossible to other methods.

Tire-Doh seals cuts and sand blisters in casings and doubles your mileage by keeping out the dirt and water which would otherwise reach and rot the fabric.

WE MANUFACTURE
18 Other Tire-Doh Products
All As Good As TIRE-DOH

Silver Quick
Stop That Radiator Leaking
Day Tire Valve
Nomore Rust Rim Paint
Blac-Namel
Sunshine Metal Polish
Everwear Nickel Polish
Metal-Lac
Renew-O Leather Dressing
No-Leak Top Dressing
X-Ray Top Dressing
Nu-Stain Top Lining Dye
Preserv-O Tire Paint
Destroy-O Carbon Remover
Sta-On Engine Paint
See-Kleer
Chemico Blowout Patch
Body Gloss

Six years on the market and the fact that Tire-Doh is repairing millions of punctures and blow-outs a year, is your best guarantee.

Tire-Doh is also effective for mending other articles of rubber—rubber boots, gloves, hot water bags, etc.

AT YO"R DEALER'S OR DIRECT FROM US $1.00

DEALERS—Tire-Doh is the standard tire repair. It is a good seller—it repeats—it is advertised. All jobbers who handle automobile supplies sell Tire-Doh.

FORD Owners!

Make Rear Axle Trouble A Thing Of The Past

Your car will hold the road in any kind of going—

You can drive with perfect freedom from side-sway and with skidding absolutely minimized—

You can pull through mud or sand where you would be hopelessly stalled with the old-fashioned differential gear—

You will save on both gasoline and tire-wear—

If you equip your car with the

Bailey Gearless Differential

These are not mere claims, but facts proven by the experience of Ford owners the country over.

The Bailey Gearless Differential gives you a positive drive on both rear wheels. The power is delivered to the wheel with positive road traction, so that one wheel cannot spin while the other is standing still.

Safety, comfort and economy—from every standpoint you need the Gearless Differential on your car. Sent complete, ready to install. Write for circular.

More Dealers Wanted

We want a dealer wherever there are Fords, to fill the demand for the Bailey Gearless Differential—a demand that is increasing rapidly, not only through our advertising, but by the word-of-mouth recommendation of users. Invariably, one in a locality means fifty more.

Write for interesting no-risk proposition.

The Most Profitable Equipment in Your Garage

Excerpt from a letter by J. A. Snyder, San Antonio, Tex.

"I think we now have had our Prest-O-Welding outfit for about 3 months, and I keep a record of all welding done, and in looking over my book I find that out of the 3 months' time I have had the outfit, can find only 7 days in which I have not had a welding job of some kind, and the boss told me only yesterday that he did not see how we ever did without it, as we could not do without it now."

PREST-O-LITE

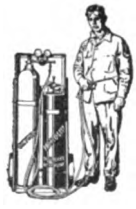
Dissolved Acetylene

(Ready-Made Carbide Gas)

Puts the process in easy reach

Even with the most moderate charges for doing oxy-acetylene repair work, the profits are too big to be neglected.

The all-round utility of any good make oxy-acetylene welding or cutting equipment is greatly enhanced by Prest-O-Lite Dissolved Acetylene. Prest-O-Lite Acetylene Service furnishes the highest grade of Dissolved Acetylene in portable cylinders, used as conveniently as you use cylinders of oxygen. Saves the large initial outlay and heavy depreciation, trouble and inconvenience of making crude Acetylene in carbide generators. Besides, Prest-O-Lite Dissolved Acetylene is perfectly dried, cleaned and purified—makes better welds and is cheaper to use.



Operation Simple—Easy to Learn

Any intelligent mechanic can master the process. We furnish full directions.

Good equipment is necessary to obtain the best results. But good equipment is not costly. It soon pays for itself. We furnish a thoroughly high-grade welding apparatus for $60. The average user will also need gas cylinders, which are extra, and about $10 worth of welding supplies. Truck and special equipment for cutting operations at extra cost.

This welding outfit is widely useful—operation extremely simple. Being portable, it can be taken to the job, thus caring for work that it would be impossible to handle otherwise.

A Highly Profitable Business for You

A wide and growing demand makes Oxy-Acetylene repair work highly profitable. Send for literature showing how you can make big money for yourself, and large savings for your customers. Necessary equipment soon pays for itself. You are losing money if you can't care for this class of work.

If you use Acetylene for ANY purpose, you should have details of the Prest-O-Lite Service Plan.

How to Keep Out of Trouble

Getting out of trouble is a matter of wits —Keeping out of it, a matter of wisdom

When your Ford gets cranky and hard to start—loses its power and flexibility, its coils need adjustment. With nothing to go by that you can see or hear, getting a set of Ford coils in good adjustment is a harder thing to do than to regulate four clocks so they will tick in unison and keep exactly the same time.

The best adjustment possible gives relief only for the time being—the trouble will come back.

—— *The* ——

CONNECTICUT MASTER VIBRATOR

FOR FORD CARS

will not only eliminate Ford ignition troubles, but will give your motor more power, greater flexibility and marked economy in fuel. Once installed, nothing can disturb the uniformity with which it delivers a hot, fat spark accurately timed for each explosion. It is a specially designed instrument—one master coil with a single set of vibrator points to time the sparks for all four cylinders.

Easily installed on either old or new models—the only Master Vibrator on the market which affords a workmanlike installation on the new Fords now coming through.

STA-TITE

There's Good Profit for Dealers Who Sell

STA-TITE PISTON RINGS

"Power to Burn—Without Waste"

They so increase the speed and power of a motor and are so economical that every user is delighted and soon sends his friends into your store for some of these wonderful STA-TITE Rings.

Made in three sections—two outer rings fitting over an inner ring—they effectually prevent loss of compression, and by keeping oil from the combustion chamber, stop waste, excessive formation of carbon and smoking.

STA-TITE Rings fit perfectly, last indefinitely, and are fully guaranteed. They sell fast because they are the best rings to be had, increase power and save money.

We also make "Quality" snap rings— cast individually—the best ordinary piston rings to be had. All sizes carried in stock.

Get our dealers' price—it means good profit for you.

N. B. ARNOLD One Bay Street, BROOKLYN, N. Y.

INLAND

1 PIECE PISTON RING

A marvel of simplicity and efficiency. Made of only one piece, it has all of the virtues of eccentric, concentric, and more than one piece construction, and none of their disadvantages.

A continuous ring cut spirally for half of its circumference, heat-treated, so that the free ends will hug tightly together. That's the construction—the result is:

An absolutely gas-tight ring that uncoils in expanding, insuring uniform pressure and perfect contact with the cylinder walls.

The strongest ring on the market, because it is made of one piece, and

1. The gap is less than 1/3 the width of the ring.
2. The free end is supported by the full depth (cross section) of the ring.
3. The friction surface of the free end is less than 1/3 its depth, making it relatively very strong.
4. It is easier to put on and will not break in handling.

The best ring on the market, at a better price. Absolutely guaranteed. Money refunded on any ring not giving satisfaction at the end of 90 days.

The Inland will be the biggest seller. Dealers and jobbers, write for interesting prices. Full description in booklet. Free.

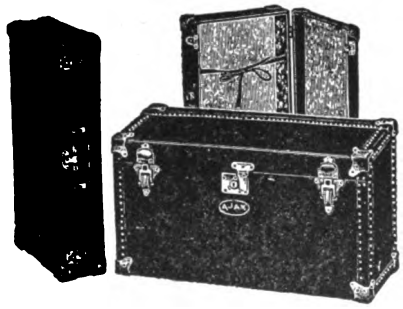
The Most Perfect Piston Rings Made

PERFECTION PISTON RINGS

They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.

This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.



PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES

REPAIRMAN

There has been a period in your life that you were unable to tell a valve from a spark plug, a magneto from a carburetor, or a cylinder from a piston; some one had to tell you what these parts were and their function. The troubles arising from these and other parts of a car, you have mastered, but you are still at sea if you do not understand and are not prepared to rebore and fit oversize pistons, for this is the most important repair that can be given a worn engine.

The HEISER IMPROVED CYLINDER REBORING TOOL for Ford Engines, makes a good shop out of a poor one and a better shop out a good one, but best of all, it gives the owner service. The end of this season will see one million Fords on the highways; this means many million dollars will be spent on reboring and fitting oversize pistons.

The early bird catches the worm. We furnish oversize pistons to fit the rebored cylinder, $1.50 each, Complete.

Write for further particulars about this wonderful tool.

Running Board Braces.

Make Your Ford as Quiet as an Electric and as STRONG as a Truck.

DOTTED LINE shows the teeter and buckle as you step on your car now.
SOLID LINE shows how rigid *CASEY* braces are guaranteed to make it.

Why not stop that rocking and teetering in your Automobile? Every time you or one of your passengers step into or out of your car (as illustrated by the dotted lines above) your truss rods, frame and fenders are strained into most strenuous contortions and then quickly released back into normal position again.

Is it, therefore, any wonder the mud guards become loosened at their fastenings and rattle or the truss rods snap off at the threaded ends?

Two dollars invested in a pair of *Casey* Braces will positively insure your Car against this abuse during its entire life. Will make your Running Boards STRONG and QUIET.

You can safely carry battery and tool boxes, entire camping or touring outfits or other loads on your running boards and there will be no strain or pull on your rods or fenders to make them LOOSE and NOISY.

The three-point suspension as used in bridge building and other metal construction, is an accepted standard, because it is scientifically right. Your Automobile will be rigid because the strain is equally distributed between the three points of support as indicated by the three arrows in the illustration, and jumping on the step with both feet cannot strain your Chassis in the least.

You can easily attach these braces in a few minutes yourself, and they will positively do wonders for your car. No drilling or fitting necessary. All you need is a wrench. Shipping weight, 4 pounds.

***Casey* Running Board Braces,** per pair complete..... **$2.**

All Cash Orders received for the next 30 days will be sent prepaid.

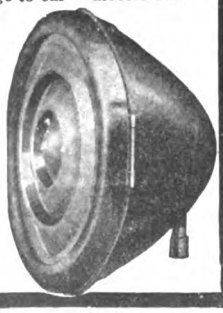
Something New From Europe

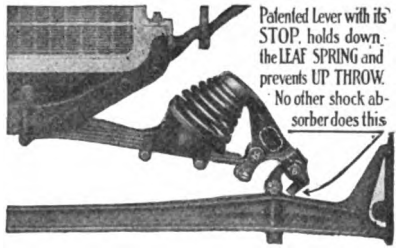
From Switzerland comes the latest and best in headlight aids—KLEARGLOW. Its popularity throughout Europe has proven its merit. This new appliance is made of scientifically designed corrugated glass surfaces in one piece. Permits touring in the country without removal, as must be done with dimmers, so as to light the dark, uneven roads sufficiently. "Dimmers" are dangerous—KLEARGLOW is safe. For city driving KLEARGLOW is 100% efficient—gives you *all* the power of the lamps without that dangerous glare. Use

KLEARGLOW
The Auto Light Diffuser

Fits any car and improves its appearance.



The law regulating headlights is strict. You can drive where you like with KLEARGLOW attached to your lamps, and *know* that you are conforming to all statutes covering this vital point.



Avoid accidents to yourself and others—damage to car—arrests and fines—by installing KLEARGLOW in place of your present headlight glass. You can try KLEARGLOW for fifteen days before purchasing if you wish. Our illustrated folder telling all about KLEARGLOW and our liberal free trial offer will interest you. Write for a copy *today*. Address

H. G. PARO
743 Michigan Boulevard Bldg.
Chicago, Ill.

To JOBBERS and DEALERS:

We have some interesting data regarding KLEARGLOW and its business-building possibilities for *you*. Just say, "Send the folder," on a post card. We'll do the rest.

The Brakes Won't Hold!

Did you ever get sucked into rapids in a canoe?

You feel the same way when your brakes suddenly fail you on a bad hill. It's the duty of every automobile dealer to impress on his customers the vital, life and death importance of good brakes. *Remember*—brakes are not infallible. THEIR EFFICIENCY DEPENDS ENTIRELY ON THE BRAKE LINING. If the brake lining suddenly goes bad—becomes friction shy—you have no more control over the car than you would have on a barrel shooting Niagara.

Thermoid
HYDRAULIC COMPRESSED
Brake Lining - 100%

Thermoid is Brake Lining all through—not merely on the surface. It is a substance which has been hammered by hydraulic compression to a uniform density—it is not a stringy, loosely woven fabric with only friction surfaces.

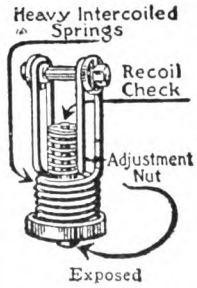
Thermoid will still hold even though worn paper thin. It is 100% brake lining.

Watch the brake lining of cars sold by you or in your care. Guard the safety of your customers by having every car equipped with Thermoid.

Thermoid Rubber Co.
Trenton, N. J.

OUR GUARANTEE:
Thermoid will make good or we will.

Cannot be burned out nor affected by oil, heat, water, gasoline, dirt.



JOHNSON
SHOCK ABSORBER

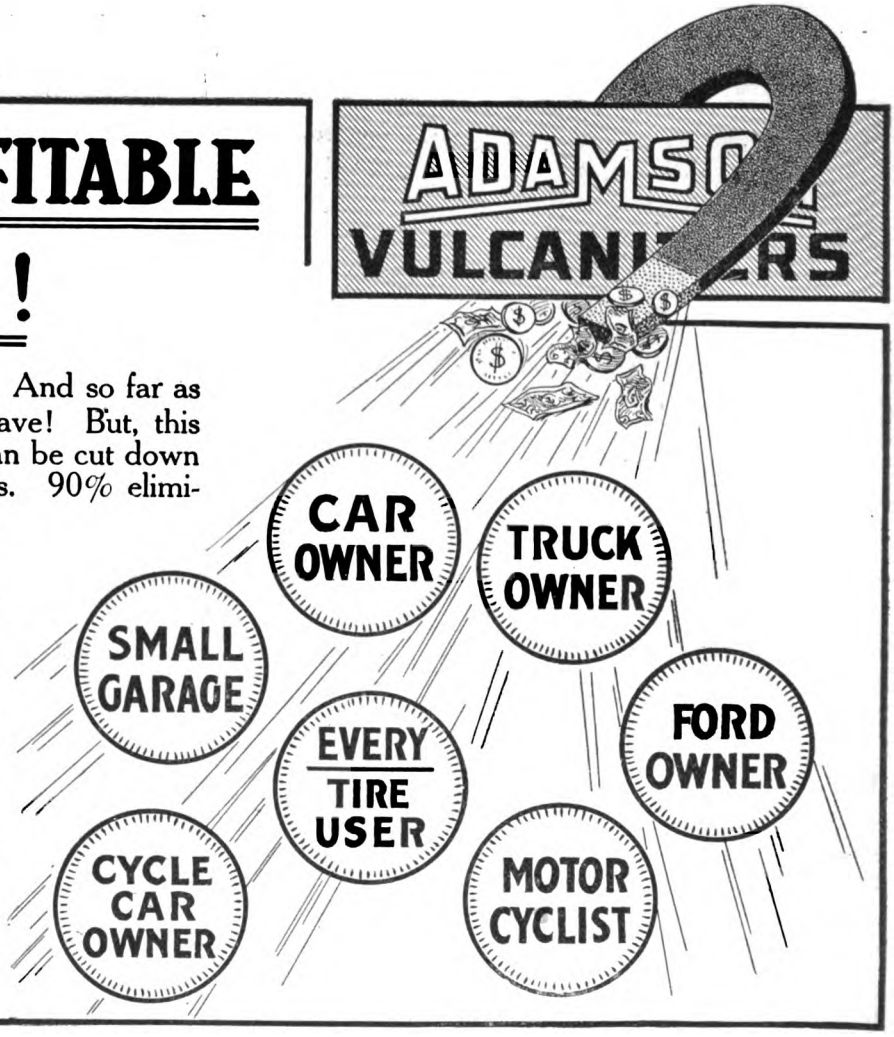
Coil spring shock absorbers are good — they improve riding qualities.

Friction shock absorbers are good—they stop the recoil—but

There is only one shock absorber that does both under all road and load conditions and that's the JOHNSON SHOCK ABSORBER.

The Only Coil Spring SHOCK ABSORBER with a Recoil Check

Ordinary coil spring shock absorbers comprise only one spiral spring—the Johnson is composed of three fast working compensating springs so interposed that all shocks big and little are simply eaten up before they reach the car.



TEN DAYS' FREE TRIAL

There is a Johnson for every type pleasure and commercial automobile. Write, giving make and model of car and we'll explain our ten-day free trial test. A splendid proposition for dealers.

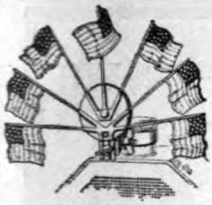
Garage Owners and Repair Men

Here's a Low Priced Vulcanizer That Does the Work

Money Back If Not Satisfactory

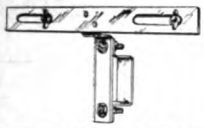
Recommended By Every User

THE SUPERIOR VULCANIZER



Simplicity in design and ease of operation. Next to these comes cheapness of operation, together with the entire absence of rubber air bags, bead molds, solid forms, etc.

To make it possible for an inexperienced hand to make repairs that will be neat and lasting, has been a study of considerable time on our part, and has resulted in a very complete little booklet of instructions which is sent with each machine. These booklets treat on tire repairs in such detail that it is practically impossible for a person of ordinary intelligence to make a failure of even his first job, if he follows the directions carefully.



The price is low and it will pay for itself in a few days.
Write for full particulars.

C-C SHOCK ABSORBER

Why *you* should sell this Shock Absorber

1st. They satisfy the customer. There are thousands of C-Cs in use today and every one is making good.

2nd. They are a quality product. All working parts are of special heat treated steel made to stand abuse. Incorporated in the C-Cs are mechanically correct features that make for efficient shock absorption.

3rd. The price is right. At $10.00 set of two, complete for the rear, the C-Cs will be attached to hundreds of automobiles in your vicinity. It is only due to enormous production that this exceptionally low price is possible.

4th. The profit for you is big because of the demand which has been created through the extensive advertising we have been doing.

Are you going to take advantage of the results of the thousands of dollars that are being spent to advertise C-Cs?

FORD MODEL $8.00 Set of Four—$4.50 Set of Two

Thousands in use today with exceptional results in comfort and reduction of upkeep expense.

Stop! throwing money away on tires

Every WORN tire you discard is money thrown away. Every one of those tires can be "half-soled," (made better than new,) in less than fifteen minutes, in your own garage—then they're good for 5000 miles or more wear.

"Pacific Treads" Save American Motorists Over $1,000,000,000 a Year

"Pacific Tread" equipment on your car will save you enough on tire bills alone in *one* year to pay all your gas and oil bills for two years.

Stop! Today

Put "Pacific Treads" on your car and you can run it for two or three years on one set of casings with this fortified "Pacific Tread" protection.

No More Blow-Outs, Punctures, Rim-Cuts or Blisters

"Pacific Treads" eliminate all Tire Trouble the minute you put them on your car.

Forget About Sliding, Slipping or Skidding

Once you put "Pacific Treads" on, your tire troubles are a thing of the past for 5000 miles or more—5000 Guaranteed.

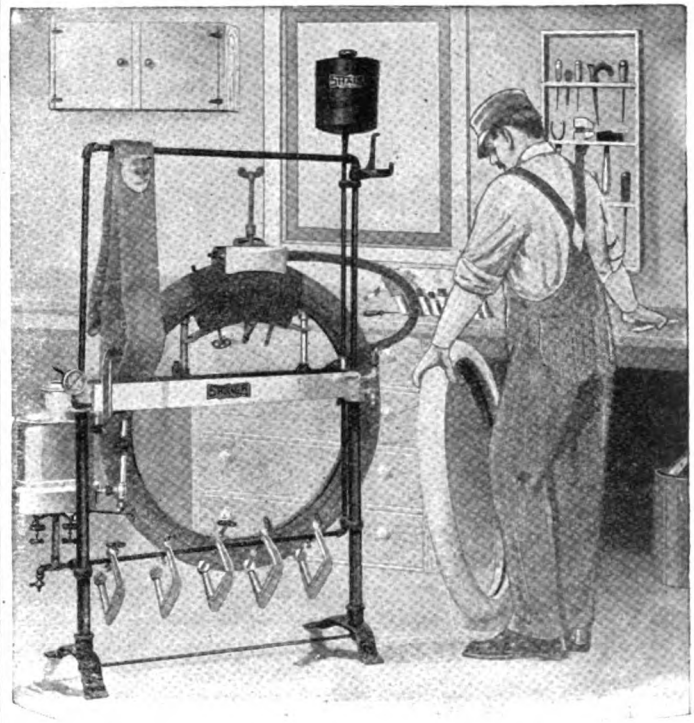
ZENITH

Ford Carburetor Gives Extra Power FREE!

The strongest selling argument for the **Zenith Ford Carburetor.** A perfect mixture at all speeds with absolutely automatic certainty. Rapid pick-up with smooth, easy "get-away" without racing engine.

A ZENITH Demonstrated is a ZENITH Sold



Once installed, the ZENITH is always right. Not a screw, spring, valve or clapper to adjust. The compound spray nozzle gives an automatic priming charge, and then adapts itself to every possible condition at every impulse of the engine, without further attention. **Nothing Like It!**

Retails at $20, with a generous profit to you. Write for proof of claims, trade terms, and selling helps.

$20

Complete with Manifold

The Motor Parts Company
SOLE PRODUCERS
818 No. Broad Street
Philadelphia

Make $60 a Week Repairing Tires

Don't be content to plod along on a small salary. Be independent. Go in the tire repairing business and make $60 or more a week. One man made $45 the first day he received his outfit. Others are making $25 a day and hundreds of wide-awake men are making $200 to $500 a month clear profit above all expenses.

Be Your Own Boss

You can make big money in the Automobile Tire Repair business. No experience needed. We teach you how. Very little capital required. But slight risk as every car owner in your town is a possible customer. Jobs are plentiful because tires blow out and puncture every day.

SHALER

Tire Repair Outfit Only $60

and will do as much and as perfect work as the big $250 to $500 vulcanizing outfits. A boy can vulcanize perfectly with this simple machine. It is the only vulcanizer that has **Automatic Heat Control.** It must vulcanize just right. It can't undercure or overcure a tire. Requires no watching or regulating. You can learn to do expert tire vulcanizing in half an hour with the Shaler.

Let Us Tell You How

to open an Automobile Tire Repair Shop and make more money. Send the coupon or a postal or a letter and get our Big Catalog and Free Book "Care and Repair of Tires." Write quick before some hustler gets ahead of you.

NOW ACKNOWLEDGED AS A FORD NECESSITY

The Comfort Safety Steering Device

Ford drivers will agree that the Steering mechanism on a Ford is incomplete.

With the aid of THE COMFORT DEVICE, drivers can overcome the difficulty of steering a Ford and can be relieved of the strain and tension invariably experienced in driving over rough and sandy roads.

The possibility of wheels "doubling under" is reduced to a minimum. It saves tires by preventing the "side lash" of wheels.

Get ALL the pleasure of driving. PRICE $5.50 DELIVERED.

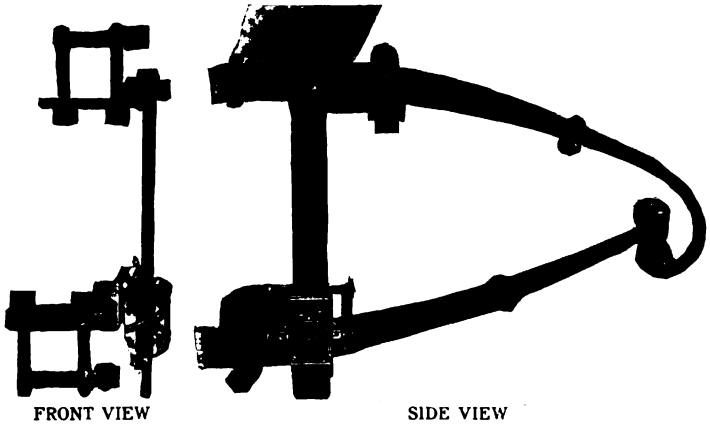
WHY REPAIRMEN SHOULD USE *Marko*

It is an easy matter to convince Automobile owners that it is economy to use the best battery that money can buy.

Probably their previous experience with unreliable batteries will enable you to prove to their satisfaction that the "Marko" is the one they should use.

Now is the time when you should go after business.



Spring overhauling is at hand and batteries for starting and lighting purposes are an important item.

"Marko" batteries lead because of their great efficiency and reliability.

Write At Once for Our Proposition to Repairmen and Dealers.

STORAGE BATTERIES

PAUL M. MARKO & CO., 1191 Bedford Ave., BROOKLYN, N.Y.

FRONT VIEW SIDE VIEW

THE car springs with the shock absorber attached are like a compound bow and arrow of great power. When the springs rebound there is a brake on the arrow or rod of the shock absorber, resulting in an easy upward movement. The shock absorber will outlast the car.

Simpler, more reliable than any other, requires no care. Money back guarantee. They are cheaper than car repairs, wear and tear, besides the ease of riding.

Reduces Sponge Cost

It gives more and better service—cannot scratch the finest car body—and is easy to handle.

The Perfolam sponge is made of lamb's wool, outer casing, and regular sponge filling. The soft yet tough lamb's wool gets the rough wear—the sponge center serves only to hold the water. The Perfolam will positively out-wear any high grade sponge by at least two to one. Used dry it is an efficient polisher.

SPECIAL OFFER: For a short time we will send you postpaid, this 7-inch $1.50 Perfolam sponge for $1.00. Money refunded if not satisfactory.

Dealers! This is a big winner. Write for lucrative dealer's proposition.

Did You Get Yours?

Have you received *your copy* of the Special Proposition we are offering to Garage Owners? If not, you are missing one of the "good things" of the season.

This Special Proposition offers you the chance to become experts in Electrical Equipment. It equips you to handle repairs and adjustments of Electrical Starting and Lighting Systems, and to gather in the large and steadily growing profits from this desirable trade.

Incidentally, it helps you to become the recognized leader in your trade in your entire district, for the control of the electrical trade will carry with it all other supplies, repairs, etc.

HERE'S THE SITUATION:

You know what Electrical Starting and Lighting Equipment has done for the Automobile—revolutionized it! It will do the same to the garage business!

If you attempt to handle this Electric Starting and Lighting repair business without proper knowledge and equipment, you will steadily lose your trade to your more enterprising and progressive competitor.

DON'T WAIT—WRITE US NOW!

We have an unusually advantageous offer to make you. Write to us *at once*, as we cannot afford to keep such a proposition open very long.

Abolishes Carbon

—surest, easiest, quickest

100% Efficient

Makes the engine—cylinders, valves, spark plugs and all—*cleanest* you ever saw. Just a *pure oil* product absolutely harmless to everything except carbon.

Takes 15 Minutes

Think of this saving of time—think how quick and how simple. Remove spark plugs, put in a little OPCO, replace them and off you go!

5c to 12c per Cylinder

Compare with prices you usually pay. Also consider the inconvenience saved. The OPCO way is so remarkably inexpensive you just can't overlook it.

GUARANTEED OPCO OIL PRODUCTS **CARBON REMOVER** GUARANTEED OPCO OIL PRODUCTS

has extraordinary MERIT—and is priced RIGHT. It's so good that the leading authorities in auto engineering and construction unhesitatingly endorse and use it. Less than 500 dealers have actually sold over 17,000 cans in 9 months.

Get Can on Approval—
or Free Booklet

So sure are we of dealer's and owner's satisfaction we want you to try OPCO at our expense. Send for trial can, prepaid; get our booklet "Carbon—Cause & Cure," anyway—use a postal.

BUFFALO, N. Y.

Dealers: Get our liberal terms

"I Want a Shaler Job on this-"

The wise motorist knows the efficiency of a Shaler repaired tire. He realizes from actual experience that when his tires are vulcanized with a Shaler they "stand up" because the repair will be strongest part of the tire. That's why he insists on a "Shaler Job."

SHALER

Electrically Heated,—Garage

Vulcanizer $65

Subject to Trade Discount

If you have electric lights in your garage this is the outfit you want. Does the same work as the big high priced machines. It repairs casings by the famous Shaler Wrapped Tread method. Tubes can be repaired simultaneously with casings. Heats from city lighting current, uses no more current than an electric iron. The temperature is controlled automatically. Impossible to overcure or undercure a tire. Each part is complete in itself and may be used independently. Takes up very little bench room.

$25 a Day More Revenue

Any wide awake garage owner can easily add $25 a day to his receipts vulcanizing his customers' tires. Your storage trade will willingly give you their tire repairing work. Storage cars alone will keep you busy. Go after this tire repair trade. It's a money maker.

Send For a Complete Catalog

Write at once for new Shaler Catalog. It's free. Investigate this extra avenue of profit for garages. You'll be surprised how easily and quickly you can add to your revenue. Steam heated vulcanizers furnished if you have no electric current. Write today. Get started while the season is on.

AMERICAN AUTO WHISTLE

SERVES TWO PURPOSES

A Loud Warning Signal That Also Protects Your Car From Thieves

When leaving your car you simply take the key with you, which leaves the whistle open so that your engine cannot be started without the same blowing loud enough to be heard blocks away.

It is a whistle that will blow for you as long as your engine goes, with just a kick of your foot, thereby giving you the use of your hands and feet in case of accident.
It is a whistle that will prove it was blowing at time of accident, if necessary.
It is a whistle that will tell you if a cylinder is leaking or skipping on your engine.
It is a whistle that cleans itself. *Write for prices and full particulars.*

MORE POWER AND A CLEANER MOTOR

Increases Mileage Per Gallon From 40 to 60 Per Cent
Decreases Fuel Cost of Operation In Like Percentage

A money saver for the user.
A money maker for the dealer.

Those who use it come back for more, and so, you Mr. Dealer, can have a steady income from its sale, if you will take up the proposition we have to offer you.

Write for FREE territory selling plans, etc. Also ask for testimonials, letters, or better still order a quart can "GASOLETTE" prepaid (it will treat 64 gallons Gasoline) and convince yourself of its wonderful merits.

Quart Can (will treat 64 gallons Gasoline)..... **$1.35**
Gallon Can (will treat 256 gallons Gasoline)..... **5.00**
Never Sold In Bulk

UNITED PRODUCTS MFG. CO.
219 EAST 22nd STREET Dept. A CHICAGO, ILL.

GASOLETTE

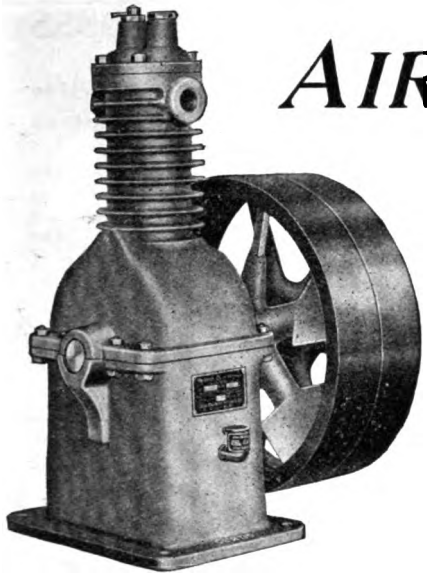
Increases the efficiency of Gasoline without injury to motors.

Gives the motor greater pulling power, more speed and 100 per cent flexibility. sparks quicker and helps the engine to almost instantly pick up and to run smoother.

Prevents pre-ignition, pounding and over-heating of engine.

Removes and prevents carbon deposits on spark plugs, pistons, cylinders and valves, and thereby eliminates engine troubles.

Prevents carbon deposits on exhaust valves and seats, thus eliminating cutting and pitting, and consequent loss of power that can be remedied only by grinding valves.



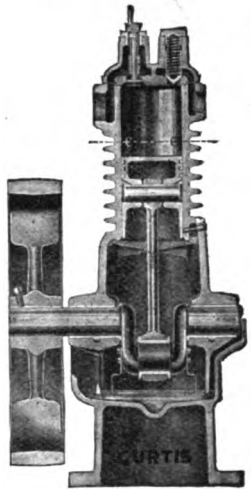
Prevents carbon Jeposits on intake valves and seats, which deposits cause loss of compression, loss of power and back firing in intake pipe.

Prevents carbon deposits on pistons, gumming and sticking of piston rings, loss of compression, loss of power—and you avoid the trouble and expense of taking down the engine to clean.

Lessens smoke, odor and noise.

Leaves cylinder and valves in an oily condition and therefore adds life to the engine.

Digitized by Google



AIR FREE FROM OIL

Unintentionally or not, you certainly will damage your patrons' tires if the air you furnish is not free from oil—but how are you going to do otherwise ?

There is only way out of it

USE A

CURTIS GARAGE AIR COMPRESSOR

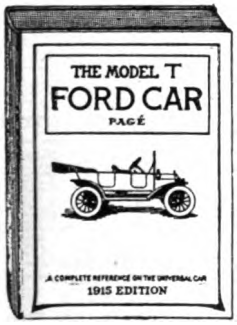
NOTE *HOW THE OIL IS PICKED UP*

A Curtis will furnish Air Free From Oil—note the cross sectional view. You will notice that unlike other splash oiled compressors the Curtis crank and connecting rod do not dip into the oil, nor is the oil thrown directly up in the cylinder—the amount of oil furnished the cylinder is limited to only sufficient to properly lubricate without excess to be carried over into the air line.

Also, you can start a Curtis Air Compressor no matter what air pressure there is in the air tank, yet use no more power (current) than if the tank were empty.

There are a lot more good features that make for cheap air.

Write us for full particulars and prices of either stationary or portable outfits



CURTIS PNEUMATIC MCHY. CO., 1530 Kienlen, St. Louis, Mo.

CHICAGO—Marquette Building. NEW YORK—30 Church Street.

A NEW, COMPLETE BOOK
FOR EVERY FORD OWNER, DEALER, SALESMAN and REPAIRMAN

THE MODEL T FORD CAR

ITS CONSTRUCTION, OPERATION AND REPAIR

By VICTOR W. PAGÉ

Member of the Society of Automobile Engineers,

Author of "The Modern Gasoline Auto mobile," etc.

300 (5x7) Pages

Over 100 Specially Made Engravings

AND TWO LARGE FOLDING PLATES

Price $1.00

This is the MOST COMPLETE and PRACTICAL instruction book ever published on the FORD CAR. Illustrated by specially made drawings and photographs. All parts of the Ford Model T Car are described and illustrated, in a comprehensive manner—nothing is left for the reader to guess at. The construction is fully treated and OPERATING PRINCIPLES MADE CLEAR TO EVERYONE. Complete instructions for *driving* and *repairing* are given. Every detail is treated in a non-technical yet thorough manner.

RAJAH GIANT

300% in One Year!

That is the increase in the sales of the Rajah Giant Plug

This Plug was originally designed for racing purposes, but its widening popularity for general use on motor boats, tractors, trucks and pleasure cars has necessitated its addition to our regular line.

In construction—with the exception that it is much heavier in the porcelain and metal parts—it is the same as the

RAJAH STANDARD PLUG

Extremely simple for cleaning: — only four parts shell, porcelain, bushing and gasket. All standard threads.

Rajah Giant Plug $1.50 } Postpaid—with
Rajah Standard Plug 1.25 } Thumb-nut Terminal

DEALERS: If you do not carry Rajah Plugs in stock, take a minute to consider how many sales you may have lost! Many thousands of car owners use Rajah Plugs only—many thousands more **eventually will!**

RAJAH AUTO-SUPPLY CO.
BLOOMFIELD NEW JERSEY

The Foundation of this Tire

is just as good as the day it was bought. Any tire with good fabric, whether there is any rubber on the outside or not, is suitable for the

TRIPLE TREAD PROCESS

The Triple Tread is the only tire protector made

that does not depend on inflation, rim pressure or mechanical means to hold it in place, so that the style of bead on your tires cannot affect the success of their treatment.

In Vulcanizing the Triple Tread on your Tire

we are able to fill the pores of the leather with rubber, making it waterproof, so that by bringing the leather down the sides and over the bead of the case, covering it completely, we are able to keep dirt and water from getting under the tread to rot the fabric, and also to strengthen the sides and bead of the tire.

Write for our booklet,

"Worn Out Tires Made New."

Please mention the size of your tires.

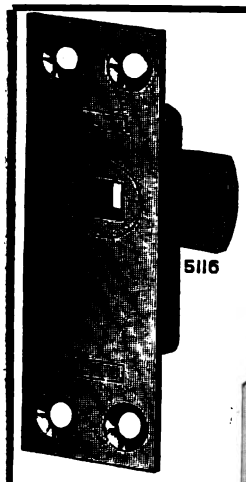
CITRUS
CUBA

Wonderfully rich land, good water, good title. Outdoor life the year 'round. A ten acre grape fruit grove will pay you $2,500 per annum for life. Eastern Cuba is to be the great winter playground of the American. The land is so fertile and accessible that fortunes are to be made in fruits and vegetables. Great country to relieve and cure rheumatism, nervous and respiratory diseases.

Present price of land $50 per acre. No frost and no irrigation or fertilization required. The young man's opportunity and the old man's paradise.



The grape fruit raised here surpasses in flavor and quality anything grown in Florida or Southern California.

The most delightful place in the world for a winter home, and very accessible. Boats sail from New York to all the principal ports, and at very reasonable rates.

DYKE'S AUTOMOBILE and Gasoline Engine INSTRUCTOR

By A. L. DYKE.

Originator of the first Auto Supplies, Publisher of the first practical book on Automobiles in America.

You learn the PRINCIPLE and CONSTRUCTION of ALL parts of ALL automobiles.

Prepared for the novice, but a handy reference for the expert.

Dyke's Automobile and Gasoline Instructor
Complete **$8.50** (add 60c. to prepay)

It teaches the principle of Automobile, Motorcycle, Marine, Stationary and Aero Engines.

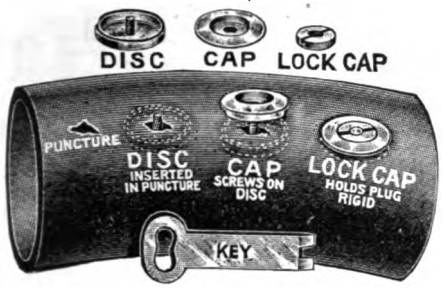
HOW TO REPAIR, ADJUST AND DIAGNOSE TROUBLES

Also covers Salesmanship

Every subject is treated, such as **ENGINES,** with all the different valve arrangements, etc. **CARBURETION**—beginning at the simplest form, to the adjustment of all leading makes. **IGNITION**—from low tension coils to high tension magneto systems. **Care of a Car;** Operating a Car: Lubrication; Building and Equipping a Garage, for home or pleasure; Self-Starters—in fact, every subject is fully covered.

VALUE OF THIS INSTRUCTOR TO YOU

WE CLAIM that with careful study of this instructor, it will enable you to become. 1) **AN ENGINE EXPERT** capable of diagnosing ignition, carburetion, valve timing, cooling troubles, and remedying them. (2) **A DIAGNOSIST** who from knowing the principle and construction of all subjects, can instantly tell the cause of any trouble and apply the remedy. (3) **A RUNNING GEAR EXPERT** capable of diagnosing and remedying such troubles as differential, transmission, axles, brakes, steering wheels and axle troubles. (4) **AN AUTO MECHANICIAN** who can adjust and remedy all the troubles after diagnosing. The subject of repairing in this Instructor is complete in every respect.



Price of ENCYCLOPEDIA, 600 pages, 1000 illustrations, $3.25 postage prepaid.

FREE—96 page Supplement with 175 illustrations on Electric Starters, Generators, Six, Eight and Twelve Cylinder Engines— with purchase of Auto Instructor.

SPITLER PUNCTURE PLUGS

(Patented May 11th, 1915.)

The Spitler Puncture Plug repairs punctures in automobile and motor cycle inner tubes quickly, and without the use of cement, assuring a safe, permanent and economical repair.

The operation is so simple that a lady can make the repair without soiling her hands.

The plug can easily be taken out and used over again. A permanent repair in one minute.

To insert The Spitler Puncture Plug into the puncture, fold the inner tube at right angles and cut the corner thus formed, making the puncture large enough to easily insert the plug. Wet the tube before inserting plug.

Place the base of plug on edge and by stretching the tube at point of puncture, the plug slides in like a button in your coat. Then place cap over discs and screw lock cap firmly.

This device fits the inner tube in a manner which prevents any possibility of injury to the shoe on tube. *Write for Circular.*

PRICE:—Automobile Plugs one inch, four to set, $1.00 per set.
—Motorcycle Plugs ¾ inch, four to set, 75c. per set.

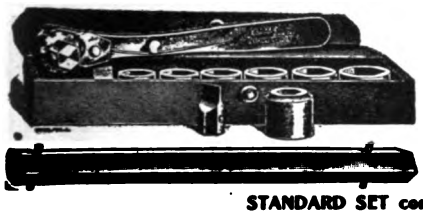
SPITLER PUNCTURE PLUG CO., Inc., United States Rubber Building, **1790 Broadway, NEW YORK CITY**

SEBASTIAN LATHES HIGH QUALITY LOW PRICES

If you delight in good tools, you will delight in Sebastian Lathes. For 25 years we have built lathes, and lathes only, employing skilled labor always, and improving equipment and machinery every year. Sebastian Lathes are

STANDARD FOR QUALITY—LOW IN PRICE

They are accurate, economical, simple and durable. Many re-orders and voluntary letters from users of Sebastian Lathes prove this.



The Sebastian reputation is back of every Sebastian Lathe. You are judge and jury when you buy a lathe. We are not satisfied until you are. Look over the complete line in our new catalog. It shows Lathes for general repair work, garage and automobile work, etc.

When you buy a lathe, say "Sebastian"

Address (for the catalog)

THE SEBASTIAN LATHE COMPANY, 108 Culvert Street, Cincinnati, Ohio

LANE'S "UNIQUE" RATCHET WRENCH

Don't Ruin Your Tire Casings

Save Them with These Rim-Cut Patches

You can prolong the life of expensive casings—you can save annoying tire changes—by applying a Goodyear Rim-Cut Patch to casings that are weakening.

Many get hundreds of extra miles from a casing this way. Many tubes are saved from blowouts. And these Goodyear Rim-Cut Patches are so quickly applied and so inexpensive. It is folly for you to drive without them. This Rim-Cut patch fits inside the casing. The patch is heavily reinforced to prevent blowout along rim, or any other cuts or likely blowout spots. Learn more about these Goodyear Tire Savers—there are 22 in all. We gladly send you book with instructions for applying. Address Desk 154

DO YOU WANT A MOTOR CLOCK

For your car, and a good one? The clock illustrated in this connection is manufactured by one of the most reliable clock companies in the country and is warranted in every respect. It is not liable to get out of order. It has interchangeable parts. It is the product of skilled labor combined with the most improved Waltham Automatic Machines. This clock is 3¾ inches high, and has a Porcelain dial 2½ inches in diameter. It has a one day movement with second hand. It can be furnished in burnished brass or nickel plated whichever is preferred. The arrangement we have made enables us to furnish **one of these clocks and a subscription to the Automobile Dealer and Repairer for a year** to all residents of the United States and its territories for the precise price the clock retails for, namely, **$2.50.** If an eight day clock is preferred send 50 cents extra or $3.00. Canadian subscribers should add **50** cents extra to cover the extra postage required on the **Automobile Dealer and Repairer.** This clock cannot be sent to foreign countries. The clock can safely be sent by mail and will be forwarded postage prepaid to any part of the country. Remittances can be made in any convenient way. Address

MOTOR VEHICLE PUBLISHING CO.
71-73 Murray Street, - - - - New York, N. Y.

Every Repair Shop or Garage
SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock** 38½ inches high, with a 12 inch dial, finished in **Oak** or **hand-rubbed Mahogany,** with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper.

Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.

The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.

Remittances can be made in any convenient way. Be sure to state whether you want this clock in Oak or Hand-Rubbed Mahogany.

A Scientific Oil Packing Piston Ring

A RING WITH A REASON

There's no mystery about "NO-LEAK-O" rings. A simple, plain, mechanical fact.

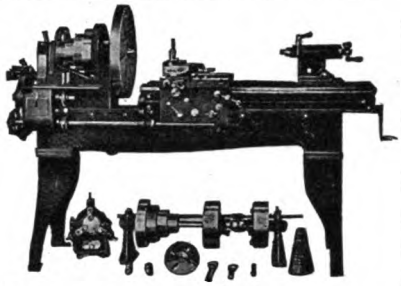
OUTING OUTING CO., (Buick Cars,) Baltimore, Md.

Writes: When you called 18 months ago about "NO-LEAK-O" Rings, I was not interested. Buick cars were giving such good service. I could not see the need of new rings. You made such strong claims we tried a set. The increase in power, saving of oil and gasoline was a surprise to us. Our repeated orders for hundreds of "NO-LEAK-O" Rings speaks stronger than we can write.

The grooves convey enough OIL to form the seal, which means perfect compression without WASTE; maximum power with less GASOLINE; perfect lubrication without CARBON, smoke and oily plugs.

We absolutely guarantee each ring for QUALITY, ACCURACY, and satisfactory service.

One Piece, Low Cost, High Efficiency.



Carbon Eliminated by Controlling the Oil.

AUTOMOBILE ACCESSORIES CO.,

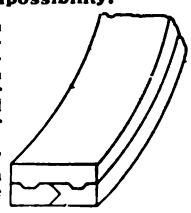
Sta-Tite Piston Rings

Are Mechanically Efficient



Sta-Tite Piston Rings are made up of three individual interlocking rings, grooved together to give Maximum Flexibility and Resiliency.

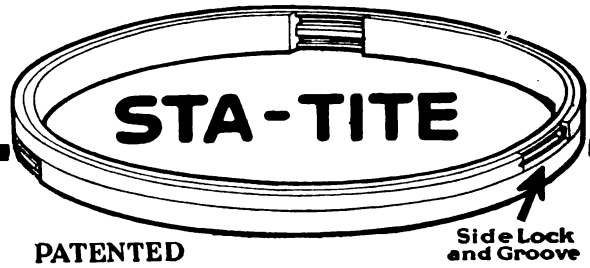
The wonderful resiliency of the Sta-Tite Ring enables it to automatically adjust itself to the width of the Piston Ring Groove.

Leakage of Compression and Oil is a mechanical Impossibility.

"Piston Ring Service Is the Key to Perfect Compression."
—Efficiency Ed.

This cross-section shows the Groove Construction which prevents the sections from slipping out of place or "riding" the pins and scoring the cylinder walls.

Prevents the "vents" or slot openings from getting in line and allowing the leakage of Power and Compression.



Install a complete set of these Mechanically Efficient Piston Rings and notice the Increased Efficiency of your Car.

Special Inducements to Dealers and Agents.

Rings in All Sizes. **Write for Literature.**

The Advantage of Local Factory Service

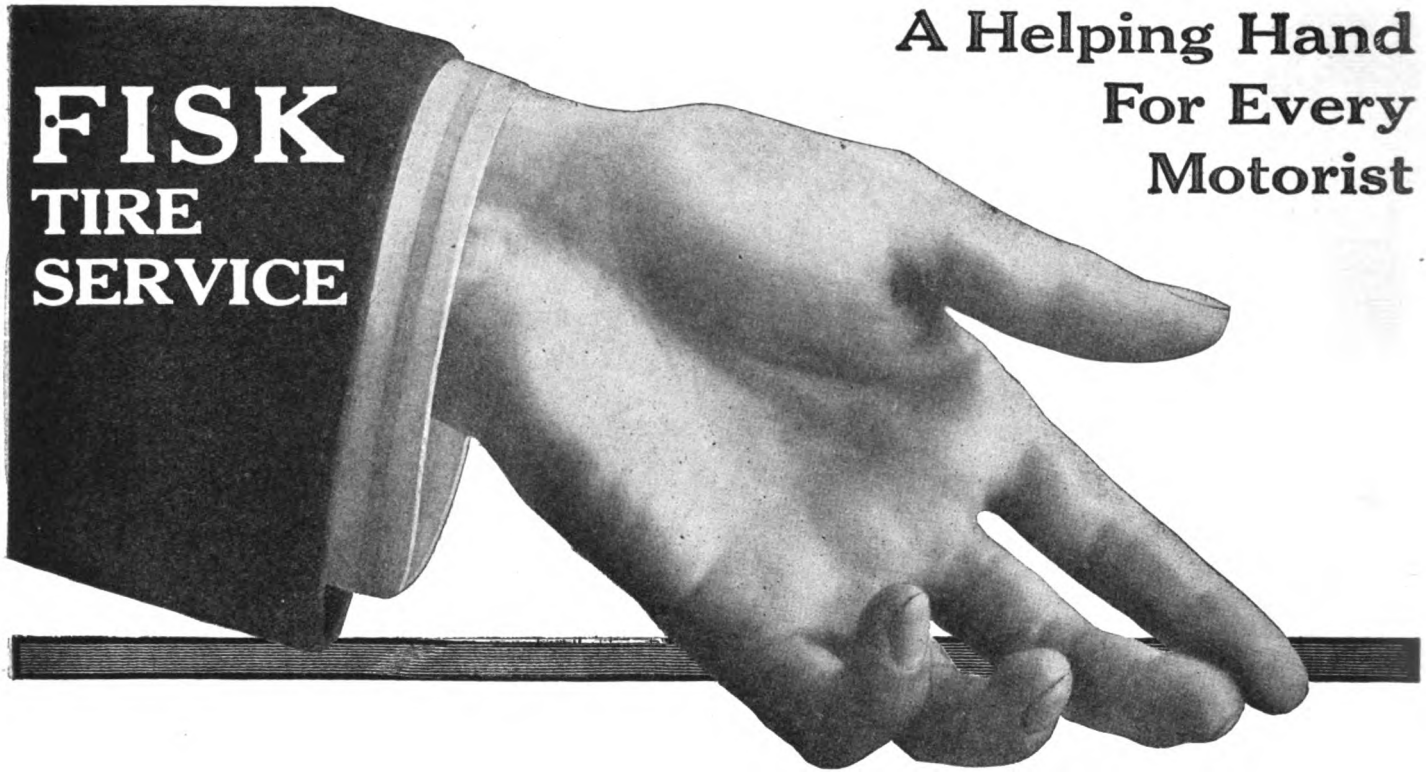
NO MATTER where your business is located our system of distribution offers you every advantage our factory in Bridgeport can give Bridgeport dealers, garage and repair men.

There are upwards of one hundred distributing organizations in the United States who carry on hand at all times a complete stock of RAYBESTOS—all sizes—a stock adequate to supply any demand, short of the requirements of a big automobile manufacturer.

TRADE MARK Raybestos REG. U.S. PAT. OFF.

The RAYBESTOS Distributor in your city or in the city nearest your town can, and will, quote you the same prices, terms and discounts as the home office and serve you to better advantage than the home office because of the saving in time and expense involved in receiving, billing and shipping your orders—large or small.

Each RAYBESTOS Distributor is, so far as business relations with you are concerned, a direct factory branch.



It will be to your benefit to take advantage of our local factory service.

The Royal Equipment Company

This Is To Be Taken Literally And Interests Every Car Owner!

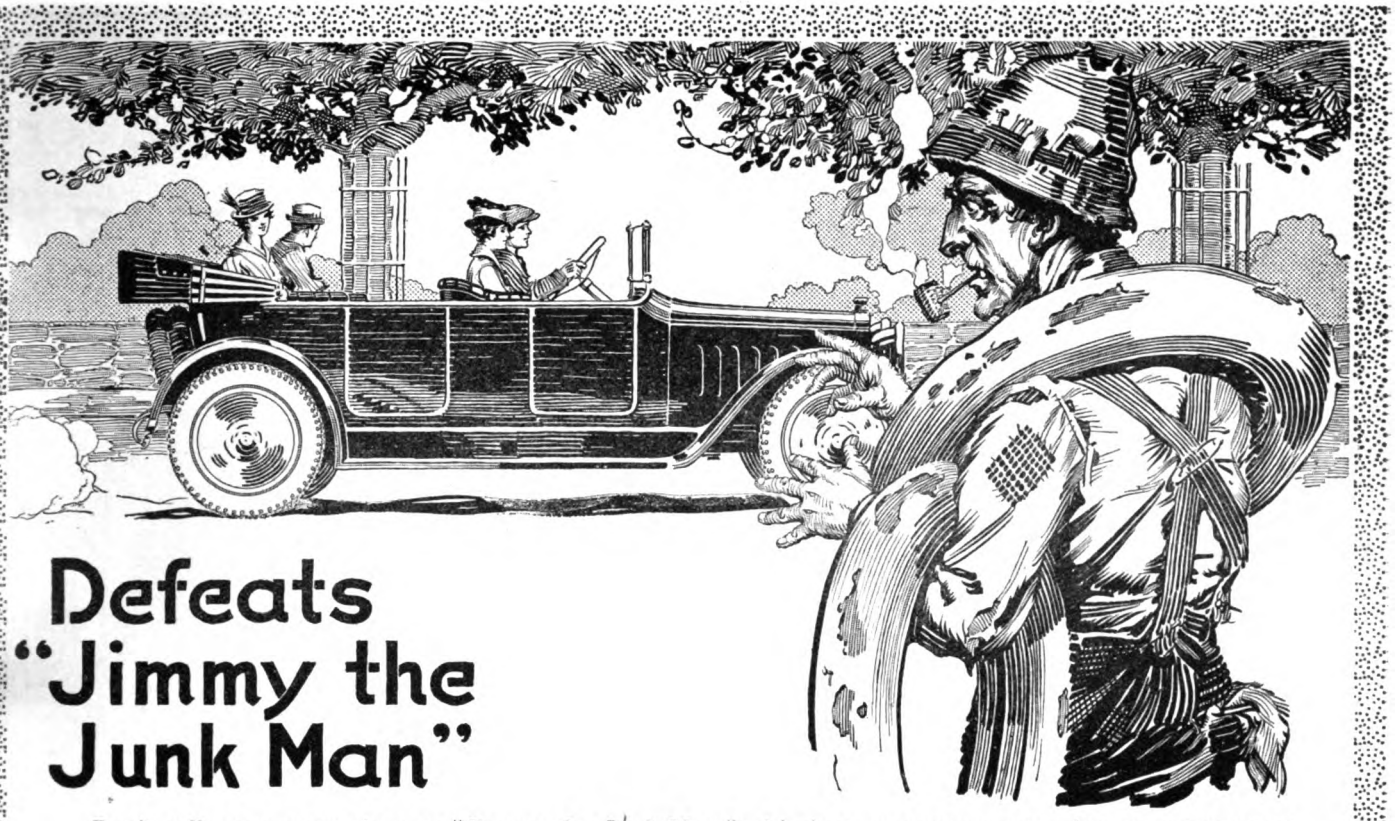
SO FAR as we can, through our Service System, we will eliminate for *any* car owner all inconveniences in the use of tires. If you use tires other than Fisk, we particularly invite you to stop in at one of our Branches the next time your tires need attention and thereby inform yourself as to the *substantial* qualities of Fisk Service.

To present Fisk Users we would say that the privileges enjoyed at your local Fisk Branch are to be found in every city where we are located. The Secret of the Success of the Fisk Service Policy is its uniformity. The Service is organized. There is nothing like it in the tire industry. We are building our business on an Established Reputation for Good Tires and for Courtesy and a Personal Interest in the requirements of *all* tire users.

Tourists should send for a list of Fisk Branch Addresses and plan to take advantage of our Service even though they may not use Fisk Tires.

Every car owner, regardless of what tire he may use, is *welcome* in any Fisk Branch. He will find there a spirit of accommodation which will add materially to his pleasure and convenience when his tires are in need of attention of any kind.

Fisk Tires Are An Extraordinary Buy



Prices are Low. There never was a time when Fisk Tires were better quality or gave more universal satisfaction. This statement can be easily verified by inquiry among Fisk Tire users.

THE FISK RUBBER COMPANY

Factory and Home Office **Chicopee Falls, Mass.**

You Can Buy Fisk Tires From ALL Dealers—Fisk Branches in ALL Principal Cities

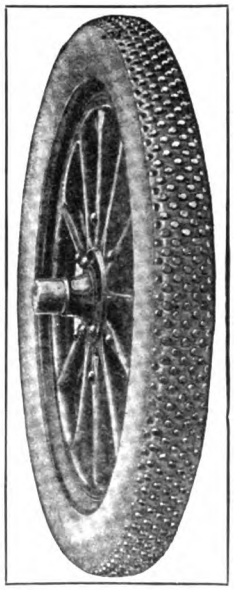
Defeats "Jimmy the Junk Man"

Don't sell your worn tires to "Jimmy the Junk Man"—it's just as unnecessary—just as extravagant—to sell your tires when they get rim cut or rut worn as it is to throw away your shoes when the first sole wears thin, for you can NOW get 5,000 miles more service out of them by doing what European motorists have done for the past three years. This will result in a saving of $50.00 to $200.00 a year for you.

What European Motorists Are Doing

For three years European motorists have been getting from 10,000 to 15,000 miles out of a set of ordinary rubber tires, while American Motorists have been getting only from 3,000 to 5,000 miles, and—what is perhaps more important—have almost entirely eliminated the constant dread of punctures, blow-outs and rim-cuts.

In the past 9 months over 20,000 American Motorists have followed their example—and are "half-soling" their tires with "Durable Steel Studded Treads" just as we "half-sole" our shoes when the original sole gets thin.



Guaranteed 5,000 Miles Without Puncture

To many motorists this fact is of more importance than the money saved by eliminating tire repair bills—the constant dread of puncture or blowouts spoils the joy of motoring. Each unnecessary noise—each bit of broken glass or sharp edged stone—each bump or "pop"—makes the man at the wheel think of tire trouble FIRST.

Durable Treads are backed by a signed guarantee—as good as a Government Bond—for 5,000 miles **without** puncture. Think of the joy of motoring when you KNOW in your own mind that your tires are **impervious** to the roughest roads—when you KNOW that **you** won't have to get out and sweat fixing a puncture or blowout, besides, you save nearly enough to pay your yearly gas and oil bills, and the guarantee holds good no matter whether your tires are new or old, rim cut or rut worn.

No More Skidding

"Durable Treads" are as sure-footed as a Rocky Mountain Burro—look at the photograph—they're simply BOUND to be safe—the sharp-edged steel rivets make skidding almost impossible. With Durable Treads on your tires you receive **perfect non-skid** service while your tires are **protected instead of injured,** and you don't have to get out in the mud and put on chains.

Strong, Sturdy — impervious to the worst roads, "Durable Treads" add a touch of distinction to any car—and make the tires the much desired over-size.

We Ship On Approval

We ship on approval to any motorist—without one cent of deposit—prepay the express—and allow you to be the judge. Durable Treads are easily applied in your own garage, without special tools, in thirty minutes.

If your tires are new then protect them from cuts and punctures by putting on Durable Treads at once—don't wait until they are all shot to pieces. **If they are old and rutworn** don't sell them to Jimmy the Junkman—remember that "Durable Treads" are **guaranteed** for 5,000 miles without puncture—no matter whether your tires are old or new.

Special Discount Offered

To motorists in new territory where "Durable Treads" have not been introduced we offer a special introductory discount. The sales of "Durable Treads" increased 917% in the United States alone during the past year—over 40% of these sales were **unsolicited**—made through the recommendation of "Durable Tread" users. Where is there **another** automobile accessory that has received such universal, country-wide endorsement?

Mail the Coupon

Let us make you a special introductory offer. Let us give you a demonstration of "Durable Treads" **at our own expense.** Let us make you an offer so fair and square that you do not stand to lose one red cent, either before or after you buy. Act NOW—don't run your tires "barefooted" another week. Tear off the coupon, sign and get it in the mail box today—if you haven't got a pen or pencil handy tear off the coupon anyway and then sign it later—it will be the means of adding 5,000 miles to the life of the tires on your car.

BOSCH MAGNETOS WIN 500 MILE SWEEPSTAKES

Every Driver in the Record-Breaking 500-Mile Race Used a Bosch Magneto

There was no difference of opinion among these close students of the motor car. They adopted Bosch Ignition without a question, not only because Bosch is more speedy, not only because Bosch is more capable, but mainly because Bosch Magneto Ignition is

Absolutely Reliable

A broad statement, but proved by facts; for not a single driver experienced a moment's trouble with his magneto during the terrific pace set by De Palma's Mercedes, the Bosch-Equipt Victor and New Record Holder.

If you want Reliable Ignition Be Satisfied----Specify Bosch

You Must Have Reliability

Your spark plugs must stand terrific punishment when you call on your motor for that last ounce of power to get over the crest of a steep hill.

The porcelain in your spark plugs must not crack under the force of those maximum explosions in your cylinders.

Champion Spark Plugs are constructed so that they take such punishment unflinchingly.

We test them over and over again, in the motor they are intended to serve, *under every conceivable strain.*

We leave nothing to chance or theory—we *make sure* of reliability.

That's why Champions give the most dependable service.

That's why we can sell them under such a sweeping guarantee.

The Champion Guarantee Complete satisfaction to the user—free repair, replacement or money back.

Dealers—Get our Profit Sharing Agreement from your Jobber's Salesman, if it is not already in your strong box.

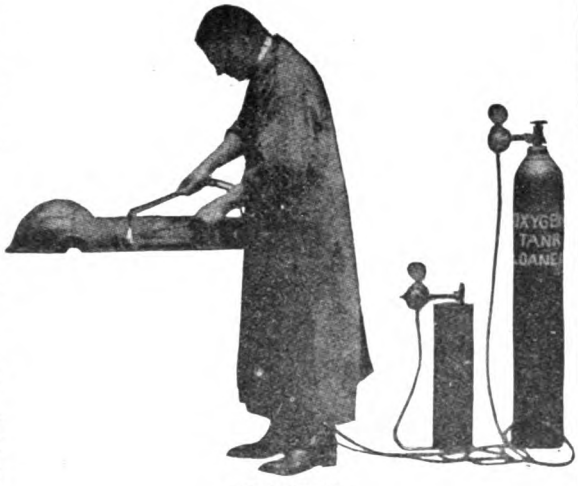
Mr. Garageman: Mr. Repairman:

$ LOOK HERE $

You need a WATERHOUSE Welding Outfit, for with it you can save broken auto parts and make them as good as new at very little cost.

To illustrate, a repairman, with this outfit, repaired a broken crank-case, which in its damaged condition was only worth 14 cents per pound as old junk. After welding it was made precisely as good as a new part, which would cost $68.

Here the repairman saved the car owner lots of money, and by so doing the car owner was willing to pay the repairman a big price for his welding, which meant big profits.



PACKED

The Waterhouse Outfit

	Value
1 B Welding Torch with 5 tips	$17.00
1 Oxygen Reducing Valve with 50 lb. line pressure gauge	10.25
1 Acetylene Reducing Valve with 50 lb. line pressure gauge	11.00
1 Set of Special Welding Hose (20 ft.)	3.00
1 Pair of Welding Glasses.	.75
1 Carbon Burning Torch..	Free
1 Set Instructions	Free
Net Cost Complete	**$42.00**

If you have a regulator for carbon burning, the oxygen regulator with the outfit is unnecessary, and you can deduct the price ($10.25), from the above total price.

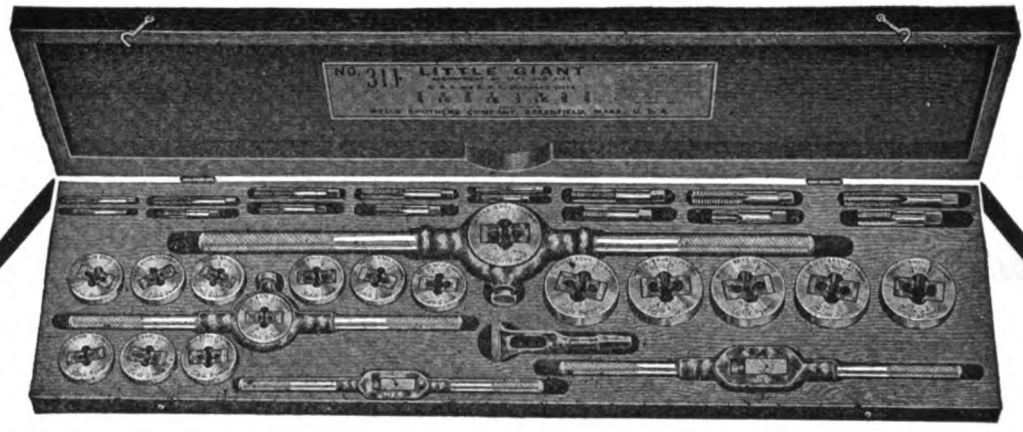
AT WORK

TERMS: 5% discount cash with order or C. O. D. or $20.00 cash with order, balance in two payments, first of $12 in 30 days, $10 in 60 days.

ABOUT TANKS

The two gases used are oxygen and acetylene. The regular automobile lighting cylinders contain acetylene, so you can use them, and oxygen can be bought in loaned cylinders at little cost.

If supplies are desired as well, we will sell for $4.50 additional the following, making you ready for any auto welding:



1 Bottle Aluminum Flux	5 pounds Cast Iron Welding Rods
1 Can Cast Iron Flux	2 pounds Aluminum Welding Rods
1 Can Copper and Brass Flux	2 pounds of Steel Welding Rods
	2 pounds Brass Welding Rods

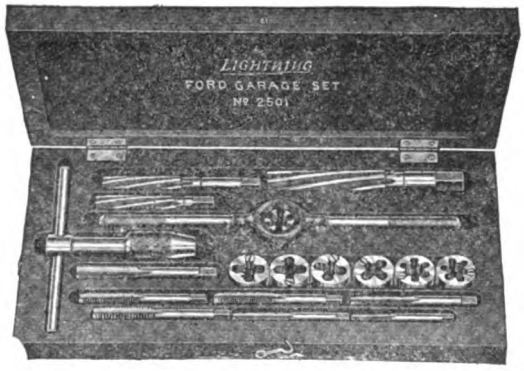
Little Giant **AUTOMOBILE SCREW PLATES**

GOOD WORK REQUIRES GOOD TOOLS

Now that the overhauling season is at full blast repairmen and garage owners need tools for cutting screw threads by hand and should have the best. Out of our large and varied list of assortments of taps and dies we want particularly to call your attention to the screw plates, one of which is illustrated above, called

Little Giant **COMBINATION ASSORTMENTS** (Containing both S. A. E. and United States Standard Threads.)



These assortments avoid the expense of buying a separate outfit for each thread standard and the expense of duplication of stocks and tap wrenches.

Little Giant **DIES CUT EASIER** Little Giant **DIES ARE MORE DURABLE**

Impossible for them to tilt or get out of alignment. Increasing the working strain only tightens the grip of the collect upon the working parts of the dies. Send for circular, "Tools for the Automobile." A postal brings it.

WELLS BROTHERS COMPANY DIVISION

LIGHTNING **GARAGE REPAIR SET FOR FORD CARS**

TAPS, DIES AND REAMERS—No. 2501

Designed especially for repairs on **Ford Cars, Model T.** A necessity for every garage and repair shop.

The Luxurious Scripps Booth is made even more attractive by Campbell Detachable Upholstery.

Adding luxury to luxury!

Owners of thousands of cars that are trimmed in finest hand buffed leather, equip with Campbell Detachable Upholstery.

Not because they are ashamed of the leather. Not because the cars are old—(most Campbell Detachable Upholstery goes on new cars,)—

But because Campbell Detachable Upholstery adds a touch of richness and comfort, a sense of luxury that no other single accessory can give. If there is such a thing as "painting the lily," Campbell Detachable Upholstery does it.

Owners of old cars, too, find that Campbell Detachable Upholstery gives new attraction and added luxury to their cars.

No matter what make or model of car you own or contemplate buying, even the latest models, you should equip with Campbell Detachable Upholstery. The cost is surprisingly low; the results remarkable. It goes on over your regular upholstery and is held in place by special simple snap fastenings so that it can be instantly removed for cleaning. Many colors and fabrics to choose from. **The Perkins-Campbell Co.,** 628 Broadway, Cincinnati, Ohio. New York Office, 89 Chambers St.

Write for Samples and Prices.

The name Campbell on the fastenings guaranteesthe genuineness of Campbell Detachable Upholstery. Look for it.

There are Two Kinds of Comfort—Body and Mind—You Get Both With

TRADE K-W MARK REG U.S. PAT OFF **Road Smoothers**

QUICKLY APPLIED TO YOUR FORD CAR

They give you the body comfort that comes ***only*** from motoring "relaxed" in a smooth riding car—regardless of the road's roughness. They give you mind comfort—that freedom from the tiring effort of steering around bumps and ruts so common to the average road. You are relieved of the nerve-racking tension of "picking the road." You get the same comfort as your passengers, plus the pleasure of "no road worry" driving.

K-W Road Smoothers give you this enviable comfort because their design combines three vital factors.

1. A spring to effectively take up the shock.
2. An anti-rebound air chamber to check the rebound.
3. Anti-side motion links to prevent side rocking and swaying.

Each of these features is in itself vital to your comfort and safety. It's only when they are combined in ***one*** device that you will get the greatest pleasure from your car. Here's how the K-W Road Smoother fills all these requirements:

The K-W Spring

A helical spring that effectively takes up the shock, made of electric smelted, chrome vanadium steel. The K-W bracket design allows almost ***twice the length of spring action*** or "travel" (in actual service) of any other.

The K-W Air Chamber

The anti-rebound air chamber with its smooth fitting piston acts like a door check, and gently "eases off" the rebound of the spring. This is an exclusive K-W feature. Its design provides a strong, tough, self-lubricating piston, working in a dust-proof air chamber. It requires no attention.

The K-W Side Motion Links

Made of the highest grade heat-treated drop forgings of remarkable toughness. This enables them to withstand the great strain put upon them. They prevent your car from pitching, swaying or skidding while making sharp turns.

K-W Bushings

All bearings are phosphor bronze throughout. That means long life.

But you can find all of these vital factors *only* in K-W Road Smoothers

K-W Road Smoothers always make good because they are built with characteristic K-W Quality throughout.

But after all's been said and done, it's results that count; and the K-W guarantee covers not only workmanship and material, but *results* as well.

$15 SET OF FOUR ONE FOR EACH WHEEL

K-W Road Smoothers are quickly and easily attached. No holes to drill and no tools necessary except a wrench. And the final and biggest advantage you get from K-W Road Smoothers is that they increase the radius of your car's usefulness, and bring you home with that "satisfied feeling" after a day of comfortable motoring.

If your dealer can't supply you, sent prepaid upon receipt of price.

How He Won Two Ajax Tire Mileage Prizes

Read how this man kept his tire expense down. Besides winning for two successive years the cash prizes which were offered to drivers obtaining exceptionally big mileage this motorist reduced his tire up-keep cost more than 60%. That is, he secured three times the usual average mileage from his tires. Other winners of cash prizes in this tire contest have written us attributing their success to use of Shaler Vulcanizer.

Of course due credit must be given to the make and quality of the tires used—but care and attention given to the tires had an important bearing on their long lives.

NEW YORK OFFICE 55 WHITE ST.

THE BOSTON STORE
CHARLES TRANKLA & COMPANY

Grand Rapids, Mich.
May 7th, 1915

C. A. Shaler Co.,
Waupun, Wis.

Gentlemen:—I just want to drop you a few lines to tell how I made $75 from $3.50. I won the 1913 mileage prize of $50 and last week I received the 1914 prize of $25 from the Ajax Tire Co., both of which I got by using one of your small $3.50 Vul-Kits to keep the small cuts repaired.

Yours truly,
R. Vlas Blom
18 S. Diamond Ave.

This Vulcanizer was bought from one of our dealers and we were unaware that user had it until this letter was received.

Your tires can just as well run from 15,000 to 20,000 miles too. They will run that far if you keep them in perfect condition by sealing the small cuts with a

SHALER Vulcanizer

The Vul-Kit

The $3.50 Investment that paid $75 Dividends

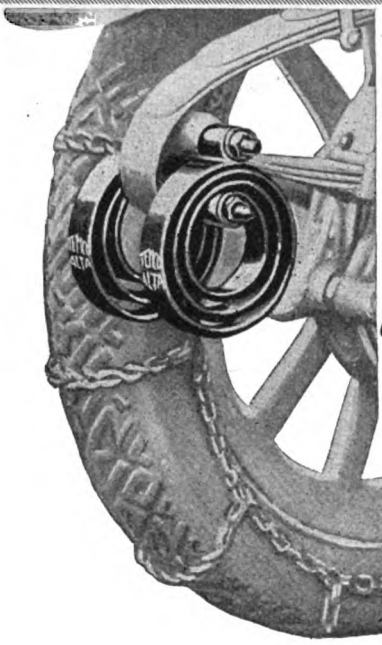
This is the Shaler Vul-Kit, the kind of Vulcanizer Mr. Blom used to aid him in getting his big mileage and win $75 in prizes. Has no exposed blaze. Absolutely safe. Burns gasoline or alcohol—an exclusive Shaler feature. No watching, no regulating. You can't overcure or undercure a repair. Handle always cool. Can be carried in tool box. Anyone can use it. Complete $3.50. Sold direct on receipt of price if you mention dealer's name.

Close up the small holes, the tiny cuts and cracks before sand and water works in. This keeps sand blisters from forming, the fabric from rotting, prevents a blowout and probably a ruined tire.

The Shaler Vulcanizer will repair these small punctures, cuts, tears, holes, rips in casing or tube and will make the repair the strongest part of the tire. It will stop tire trouble and expense, save your tires, save repair bills, increase your mileage and prevent tire trouble by vulcanizing the small cuts and holes.

Free To Motorists!

"Care and Repair of Tires"



Every motorist who is interested in increasing his mileage should have a copy of this valuable tire book. It explains everything about tires. Contains valuable hints and suggestions and shows you how to overcome every kind of tire trouble. Send for a copy today, it's free.

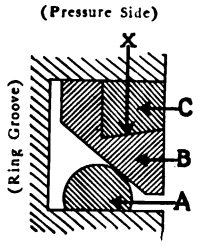
THE TRUTH ABOUT PISTON RINGS

New Features of Piston Ring Construction You Cannot Afford to Overlook



WHY PISTON RINGS LEAK

Piston Rings may leak from one or more of the following causes:

1. Poor fitting in ring groove when installed.
2. Wear of the ring and groove while in service.
3. Imperfect contact of rings against cylinder wall, due to unequal radial expansion, also distortion of rings by stretching when applying. Also loss of tension in ring material.
4. Unsealed openings on **side** of rings where they bear against **face of ring groove,** allowing leakage **under** the ring.
5. Unsealed openings on face of ring bearing against cylinder wall.
6. Broken rings, and scored cylinders due to broken rings.

The Pressure Proof Ring Constructed to Remedy These Faults

1. The **PRESSURE PROOF** ring is self adjusting, the expander A being variable on bevel of ring B according to groove width, up to 1/32 of an inch large. No fine fitting necessary.
2. The **PRESSURE PROOF** ring does not wear loose, as wear is taken up as described in No. 1.
3. The **PRESSURE PROOF** ring has even tension at all points on cylinder wall, because it is made the size of cylinder, therefore it is a perfect fit. Other rings are made larger and compressed to secure tension. In the **PRESSURE PROOF** tension is obtained by the expander A pressing equally in all directions on the beveled ring B (see sectional cut) producing tension outward against cylinder wall and against side of ring groove, thus securing and **maintaining** an absolutely tight joint. As the ring is neither opened nor closed, it is under no strain whatever. Owing to the distinctive construction, the **PRESSURE PROOF** ring is applied without stretching over the piston (see cut of piston). One ring has been applied over 1000 times without breaking.

4 and 5. The **PRESSURE PROOF** ring has no unsealed openings, therefore there is no opportunity for pressure or oil to leak under the ring.

6. The **PRESSURE PROOF** ring is under no strain whatever, and never breaks in service. The spring expander takes the strain and the cast iron rings do the packing.

The Pressure Proof is the only Self-Adjusting Piston Ring, and will produce results impossible to secure with any other ring.

The manufacturer has devoted many years to the perfection of metallic packings, and a large number of satisfied users is ample proof that the **PRESSURE PROOF** ring is thoroughly practicable and reliable. All rings are sold on a basis of money back if not satisfactory after 30 days.

DEALERS: We have the best yet in piston rings. If you are progressive and keep up with the times, write now.

PRESSURE PROOF PISTON RING CO., 3368 Washington St., Jamaica Plain, Boston, Mass.

To install **PRESSURE PROOF PISTON RINGS** in a motor means that that motor will thereafter work at the highest degree of efficiency possible to obtain, and we stand always ready to adjust, to help, to advise, in fact, to guarantee in the highest sense of the word. Can you afford to accept by-gones any longer?

What's the Answer to the Touring Question?

But they can't give you the greatest enjoyment the most comfort—and freedom from excessive tire bills—unless they're on your car.

IF ALL roads were smooth as billiard tables; if there were no ruts or thank-ye-ma'ams—no tracks, cobblestones or rough streets to jolt and jar; if all roads were ideal it would not be necessary to equip with strong, sturdy and rugged Miller Tires.

But roads are far from being ideal. The man who wants the most pleasure from his car, must select the tire built to give him the utmost in mileage, safety and service under all road conditions.

All Roads look alike to Miller Tires

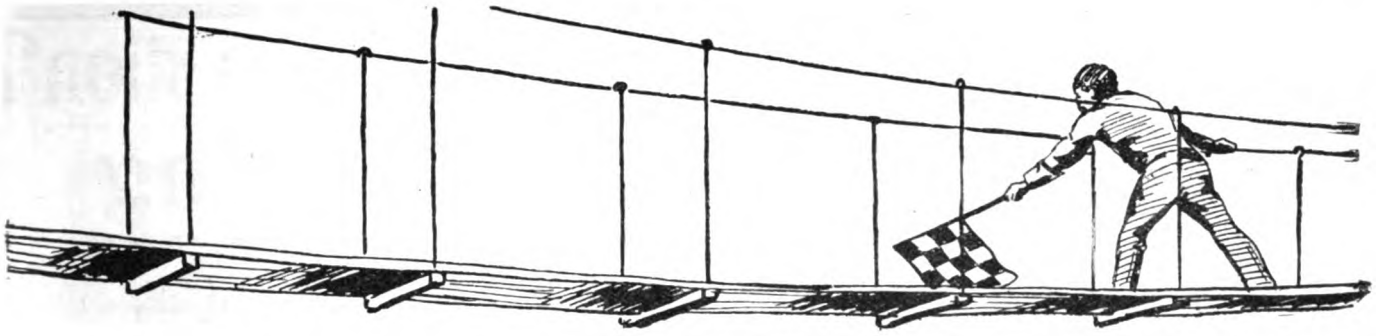
because the exclusive Miller Method of building tires does not cook the life out of either fabric or rubber in vulcanizing! Life in the cotton fabric means miles on the road. ***The Miller Method retains the natural vegetable wax and oil in the cotton fibre for wear in your tire.***

This natural lubricant carbonizes at 240 degrees. The old method of vulcanizing requires about 287 degrees to properly vulcanize a tire. And a brittle and lifeless fabric, with the power of resistance gone, results in short mileage on the road.

But the Miller Method of vulcanizing with a low degree of heat—overcomes all that.

And just as this exclusive Method retains the natural vegetable wax and oil in the fabric, so does it conserve all the toughness and wearing qualities in the rubber. Thus it makes a rugged unit of both rubber and fabric—without carbonizing the wax and oil in the fabric—or cooking the native endurance out of the rubber.

The result is a tire that insures practical immunity from blowouts and irritating road-side repairs.



Get yours from the Miller dealer today, and make touring what it should be—a constant pleasure.

If you don't know the Miller Dealer in your town, it will pay you to write us.

ANOTHER "NORMA" VICTORY

In the fastest, hardest race ever run—the Indianapolis Sweepstakes on Memorial Day the winning cars, and all the cars that finished, carried magnetos equipped with "NORMA" Ball Bearings.

In this—as in all the great races of recent years both in America and abroad - the unequaled speed qualities and service capacity of "NORMA" Ball Bearings have been demonstrated by their performance in the magnetos of the winning and finishing cars. It is this character of performance which has made "NORMA" Bearings the standard in most of the high-grade magnetos, lighting generators and starting motors of today.

Are **your** electrical accessories "NORMA"-equipped?

ATTENTION, FORD OWNERS!

THE NEW YORK AUTOMATIC HEAD LIGHT CONTROLLER FOR FORD CARS

PRICE $5.00

(Patent applied for)

Delivers a powerful light at the lowest engine speed. Uses the Regular Ford magneto, requiring no batteries or complications. **Entirely automatic in its operation**—no belts, gears, or movable connections to the engine are employed. **It also prevents the bulbs from becoming burned out at excessive engine speed.** This is positively the first and only solution to the electric head light problem on Ford cars. We furnish necessary wires already connected so that anyone can install in ten minutes by the simple removal and replacing of one bolt.

You need one—Why delay. Send us $5.00 with the understanding that you may return the device if you desire.

Install a New York Master Vibrator On Your Ford Car

and enjoy the smooth, evenly applied power so noticeable in six cylinder engines. It is immaterial if your car is the latest or oldest model—our vibrator dispenses with all coil adjustments, insuring easy starting and a hot, perfectly timed, powerful spark under all conditions. The proven standard for the past six years.

PRICE $10.00

With fittings to install on the new 1915 models.

Prevent your Ford from being stolen

by buying

OUR NEW YORK KICK SWITCH WITH YALE LOCK—PRICE $2.50

which fits the new Ford metal or wood coil boxes. This is a handsomely constructed Kick Switch containing a genuine Yale Lock, which affords the convenience of the regular Kick Switch, but possesses the locking feature which is found in no other type.

Anyone can install—Remit $2.50 today—Money back if not satisfactory.

Two Ignition Systems for Ford Cars

The New York UNI-Coil Ignition System for Ford Cars. Price $15.00

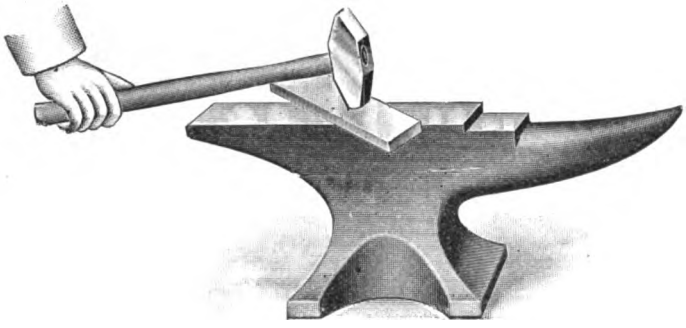
Operated by the Ford Fly Wheel Magneto (or Battery).

This system is primarily intended to operate on the Ford fly wheel magneto. It consists of a well-made elevating gear bracket upon which our Combined Timer and high tension Distributor is mounted. The Distributor is of the most simple construction containing the essentials of the high tension magneto. It uses one unit equipped with vibrator of your regular Ford coil. It dispenses with the timer and practically all of your present wiring, insuring a perfect timed spark and freedom from trouble.

The only satisfactory distributor system for the Ford magneto. Furnished complete to the smallest detail.

THE RHOADES BATTERY IGNITION SYSTEM

is intended for the class of Ford owners who prefer to **dispense entirely with vibrators.** This system operates entirely on battery, six dry cells supply ignition for from two to four thousand miles. We supply a **handsome non-vibrating coil** fitted with Kick Switch, also elevating gear bracket. Six years of hard service have proven it to be the best battery system obtainable for Ford cars.



PRICE $20.00

Take the Slant Out of Hills

THOSE hills your car used to take so easily on high, that now seem to grow steeper every time you try them. Even in second you find it more and more difficult.

The piston rings in your motor are giving out. They are worn and fit badly—they leak compression. You can't get full power with them.

LEAK-PROOF
Piston Rings

Made by McQuay-Norris Mfg. Co.

will take the "slant out of the hill" by restoring proper compression and making each fuel charge deliver maximum power.

The two-piece, angle-to-angle interlocking construction of the LEAK-PROOF Ring is the only mechanical principle securing equal, firm and sustained bearing on the cylinder wall, while preserving exact fit to piston head. Identify the genuine LEAK-PROOF Ring by this exclusive feature. Be sure you get it when you ask for LEAK-PROOF.

ROMORT AIR NOZZLE---CUSHION CLEANER

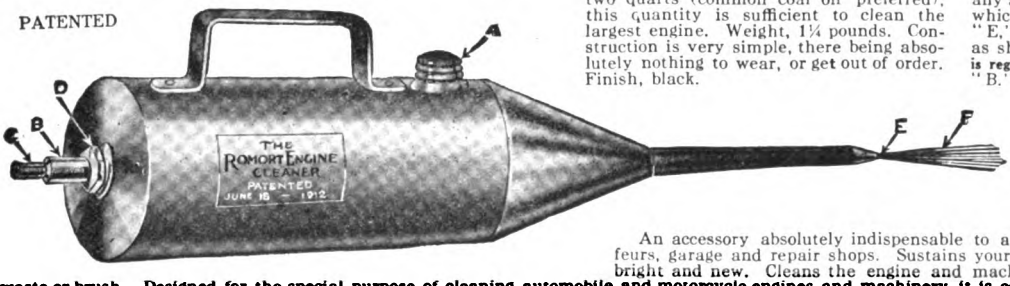
Price 25 Cents Each

The handiest little device ever invented for the purpose of **blowing the dirt and dust off cushion tops, foot mats, machinery, etc.** When attached to a Romort Automatic Air Valve, or Pump Connection, air flows out of the needle point **with terrific force**, forming a perfect and effective Air Cleaner. Ask your Dealer, or order direct.

ROMORT PUMP CONNECTION RUBBER---or ROMORT RUBBER WASHER

FITS ALL VALVES AND PUMP CONNECTIONS

One Dozen Rubbers to a Carton **Price 25 Cents per Carton**



A scientific Romort design, made of a Special Compound of Rubber (not dope), has the best wearing qualities. Easily slips on the tire valve, **Will hold fast and will not turn inside out. Don't be misled by cheap inferior washers similar to Romort design—Genuine Romort Rubbers are stamped "Romort."** Leading Jobbers and dealers carry **Romort Rubbers** in stock—if yours don't, fill out Coupon below.

The Romort Engine Cleaner

PRICE $3.00 Each

PATENTED

DESCRIPTION

The Romort Engine Cleaner is 20½ inches long by 4 inches in diameter, a convenient size for carrying in a car. Fluid capacity, two quarts (common coal oil preferred); this quantity is sufficient to clean the largest engine. Weight, 1¼ pounds. Construction is very simple, there being absolutely nothing to wear, or get out of order. Finish, black.

HOW TO OPERATE

Fill the tank as shown in the cut at letter "A," attach the cleaner to hose or air supply at letter "C," (standard connection will fit any air hose). Turn knurled rod at letter "B," which opens valve and lets fluid out at letter "E," fluid is forced out in a very strong spray, as shown by letter "F." **Light or heavy spray is regulated** by a slight turning of knurled rod "B." The packing nut, as designated by letter "D," may be easily detached and repacked if found necessary.

NO DANGER OF EXPLODING

As the air does not enter the tank, but passes right through, picking up the fluid at letter "E," there is absolutely no danger of the tank blowing up—this being impossible.

An accessory absolutely indispensable to automobile and motorcycle owners, chauffeurs, garage and repair shops. Sustains your car efficiency by keeping the machinery bright and new. Cleans the engine and machinery perfectly without the use of rags, waste or brush. **Designed for the special purpose of cleaning automobile and motorcycle engines and machinery, it is constructed with a long spout or point, so the operator may easily reach every nook and part of the machinery, an impossibility with the old method of rags and waste. The dirt and grease readily disappear before a strong spray, which works under a very low air pressure. Use an engine-driven or spark plug pump, garage storage systems or in fact any air pressure system from 10 pounds to 200 pounds. It cleans the machinery of your automobile or motorcycle just as readily and with the same result as one would hose off the outside of the car. The Romort Engine Cleaner, one quart of coal oil and five minutes of your time will do the work.**

For sale by all up to the minute Dealers or order direct—See Coupon attached.

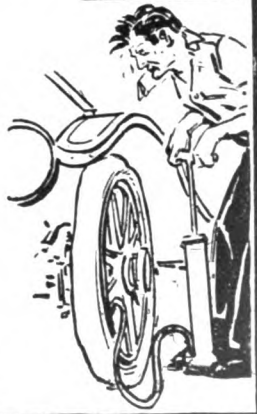
Let The PURAIR TIRE PUMP DO IT!

Pumps While You Smoke!
"FREE" AIR ANYWHERE

The joy-killing, back-breaking hand pump is a LOSS!

THE BEST POWER PUMP—NO OIL, NO GUESSWORK

May be installed by anyone, as no machine work or special tools are required. A simple, durable pump that will inflate your tires to required pressure then pop off with a loud noise, no gauge necessary.



Perfect Inflation! Very few succeed in pumping up their tires to required pressure with a hand pump; the last ten pounds count the most but are hardest to get.

The PURAIR PUMP does the work in a minute or two. Proper inflation of tires means more mileage, less blowouts and longer life.

The PURAIR PUMP garage outfit should be in every garage—handy, convenient, a necessity. Price **$55.00,** Complete with Motor and Accessory.

PURAIR PUMPS, ready to attach to cars, single cylinder **$12.50,** double cylinder **$16.50,** Ford Special **$7.00.**

Attached to your car by a bracket and connected with engine.

EVERY FORD NEEDS A WALDEN WORCESTER WRENCH

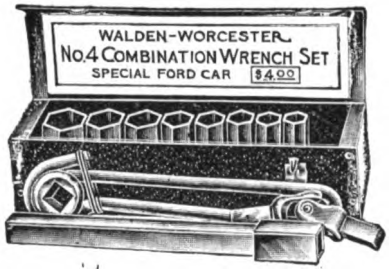
MR. FORD OWNER

Walden-Worcester wrenches for Ford cars have been built *specially* for use on the Ford. They are designed to meet the hardest service. Every wrench is *guaranteed*. Your money back, if it fails to do the work required. If your dealer tries to substitute and hand you a cheaper tool, demand the **Walden-Worcester**—(Look for the name on the tool and get your money's worth. Insist on a **Walden-Worcester.**

No. 1620—Triple Socket Wrench for Cylinder Head and Housing Bolts

The most useful single wrench for Ford cars. Cylinder head bolts, rear axle nuts and housing, water intake pipes and sundry other places. The offset gives necessary leverage for tightening or releasing bolts, the tee handle feature being wonderful for quick work.

PRICE **38c**

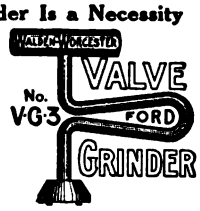


No. 4564—For Reverse and Brake Bands

The only wrench for use on brake and reverse bands, giving a full clearance around nuts. The peculiar shape of the handle allows full working space at all times. A Ford car is not complete without one of these wrenches.

PRICE **50c**

No. 4—The Set That Fits Every Bolt and Nut on Fords



A complete outfit that enables you to reach *every* nut and bolt on the Ford. It is the strongest, simplest, best constructed ratchet wrench set ever devised. Every part of this set is made for service and absolutely guaranteed against defects. With this outfit you are prepared for any emergency. Every Ford owner endorses it. It will pay you to invest in one of these sets today.

PRICE **$4.00**

A WALDEN Valve Grinder Is a Necessity

Consists of a special brace having a grip hold attachment that fits into the Ford engine valves. Will grind Ford valves better and in less time than any other valve grinder on the market. Made of Bessemer Steel Rod. You will like this little tool and will be glad to recommend it to your friends.

PRICE **30c**

ASK FOR OUR LATEST CATALOG

We have a money-making proposition in our new catalog that will be of extreme interest to you. It's something you have always needed. It will pay you to write. Just say, "Tell me about that 'box' you are giving Free."

MR. FORD DEALER

Walden-Worcester wrenches for Ford cars are *big sellers*. They are the most practical, most reliable tools that you can handle. Every Walden-Worcester specialty is backed by a *guarantee* that protects you and your customer. Why sell inferior, unreliable tools when you can sell the *best* at the same price? You will make *more* money in the long run by giving your customers **Walden-Worcester Wrenches.** Ask for our Wholesale Price List.

No. 5810—For the Connecting Rods

A tool of the greatest practicability and service, one that reaches any position without removing the motor from the car. Its peculiar shape affords splendid grip and powerful leverage No Ford owner should be without one.

PRICE **35c**

No. 1824—Double Socket Wrench

A splendid double end wrench for removing main bearing and engine base bolts, etc. Sockets are of different size and are steel machined. They are case hardened and applied to the rod by our special process. Guaranteed not to twist or shear off.

PRICE **35c**

The Most Perfect Piston Rings Made

PERFECTION PISTON RINGS

They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.

This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.

PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

IMPERIAL WELDING AND CUTTING EQUIPMENT

OXY-ACETYLENE PROCESS

Meets Any Emergency!

In the shop or on the road—for welding cracked cylinders, broken aluminum cranks, transmission cases, crank shafts, frames, axles, rear axle-housings, steering knuckles and all other automobile parts quicker, more effectively and *considerably cheaper than you ever have done before.* Removes carbon from engine cylinders in a jiffy. Imperial Equipment pays for itself in one or two operations. Safe, compact, reliable, portable; can be moved anywhere—*always ready.*

You Too, Can Do This!

This picture has money-meaning value to garage men. A broken axle out on the road—five miles from a repair shop. Instead of hauling the car back to the shop this progressive garage owner puts his Imperial Outfit and an oxygen tank in his runabout—drives quickly to the job—hitches it to the acetylene tank used for lighting—and *in a few minutes* the axle is as good as new, *without dismantling car.*

Imperial Equipment is indispensable in the garage.

Write Today!

Ask for prices, catalog and full details. *Prove to yourself* how you can save enormously in time and money with Oxy-acetylene Welding and Cutting Equipment.

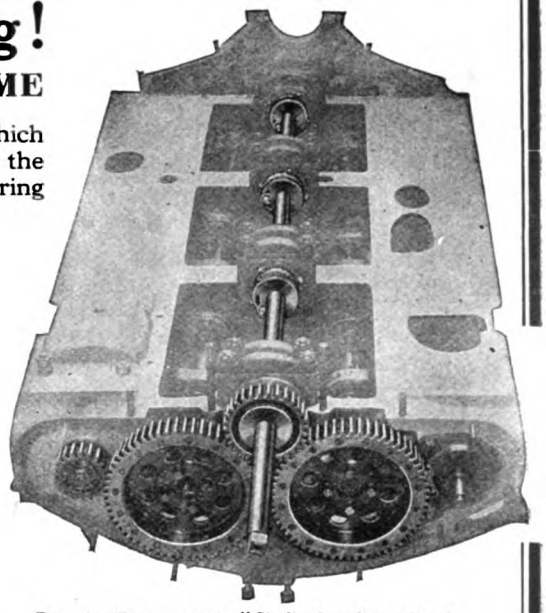
This REAMER For Motor-Bearings

Will Abolish Hand Scraping!



DOES BETTER WORK—TAKES 1/4 THE TIME

Do you want to learn about a reamer for motor bearings which cuts out three-fourths the time of hand scraping, which aligns the bearings perfectly and which lets you double your profit on bearing work? Then write for our booklets describing the

MARTELL
ALIGNING REAMER

This wonderful new tool revolutionizes bearing methods. It was invented by an engineer who was tired of the slow, tedious, hand-scraping method. It BORES the bearing to size (micrometer adjustment to .001") and BURNISHES the bearing surface, insures accurate meshing of gears and leaves the bearings in absolute alignment. You can charge your customer less, but make more profit yourself on work of this kind.

Set No. 1 for ordinary motors having bearings from 1 5-8 to 2 1-4 inches.
Set No. 2 for small motors, bearings from 1 1-4 to 1 5-8 inches.

Reaming Bearings on a "Six." Cut shows Crankshaft Gear in Position on the Reamer Shaft.

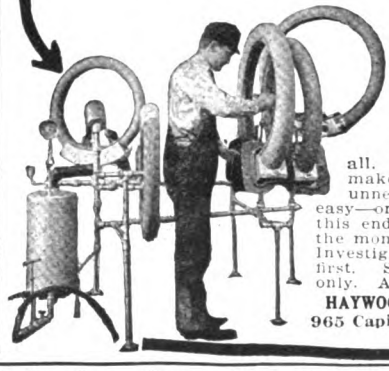
Add $250.00 A MONTH EXTRA To Your Business



REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large** and **returns quick and all cash,** besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT

Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.

HERE IS YOUR OPPORTUNITY

Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service—repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

"Bridgeport"

BRASS CO. TRADE MARK

A Bridgeport Pump For Any Size Tire

The merit of a tire pump may be determined by the amount of effort that pump requires to inflate a tire — the larger the tire, the more apparent the difference in pumps will become.

From Ford size tires on up, they all look alike to the man who carries a Bridgeport Pump.

We know we make and sell by far the greatest number of Automobile Tire Hand Pumps — if not more than all other makes combined. We believe that the size of our business is due solely to the superiority of

BRIDGEPORT PUMPS

in materials, in workmanship, in efficiency and in ease of operation. And just because a Bridgeport Pump will give infinitely better service than any other—and that kind of service indefinitely—be sure you get a BRIDGEPORT.

Bridgeport Brass Company

BRIDGEPORT CONNECTICUT

INLAND

1 PIECE PISTON RING

A marvel of simplicity and efficiency. Made of only one piece, it has all of the virtues of eccentric, concentric, and more than one piece construction, and none of their disadvantages.

A continuous ring cut spirally for half of its circumference, heat-treated, so that the free ends will hug tightly together. That's the construction—the result is:

An absolutely gas-tight ring that uncoils in expanding, insuring uniform pressure and perfect contact with the cylinder walls.

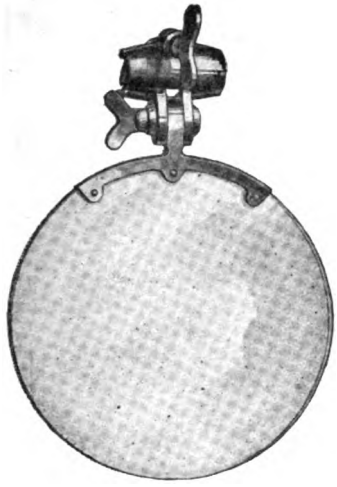
The strongest ring on the market, because it is made of one piece, and

1 The gap is less than 1/3 the width of the ring.

2 The free end is supported by the full depth (cross section) of the ring.

3 The friction surface of the free end is less than 1/3 its depth, making it relatively very strong.

4 It is easier to put on and will not break in handling.



The best ring on the market, at a better price. Absolutely guaranteed. Money refunded on any ring not giving satisfaction at the end of 90 days.

The Inland will be the biggest seller. Dealers and jobbers, write for interesting prices. Full description in booklet. Free.

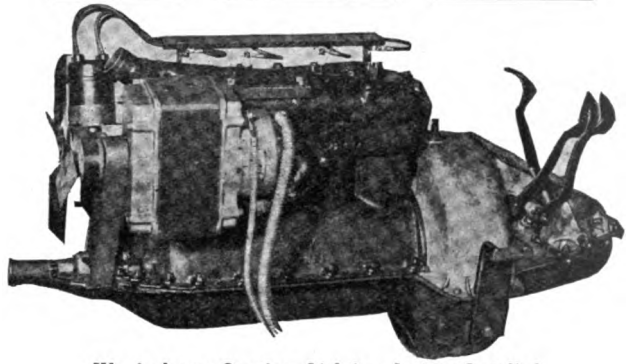
THE STAUDE GLARE STOPPER

$2.50

Nothing succeeds like success. The Staude Glare Stopper is the sensation of automobile accessories for the year. Motorists are going wild over it.

Placed on any windshield it protects the driver from the glare of approaching headlights.

The Staude Glare Stopper consists of a 6⅞ inch disk of the finest imported amber plate glass securely fastened after the fashion of rimless eyeglasses. The amber glass dissects the light rays and eliminates all the glare and dazzle.



Once the Staude Glare Stopper is attached to a machine, it is never taken off. It fits without a rattle, and looks trim.

If you are not already handling the Staude Glare Stopper, write us at once for dealer or jobber prices. Send us the retail price ($2.50) for one. Try it out on your own car. Then if you are not convinced that no motorist can do without the Staude, return it and we will refund your money. With your first order of a quantity we will refund the difference between the retail price and dealer or jobber price on the one you have.

Woodworth Trouble-Proof Tire

A Puncture-Proof Tire That Is Resilient and Non-Heating

The Woodworth Trouble-Proof Tire has no metal or other stiff material in it to make it ride hard or generate excessive heat. A strip of flexible chrome tanned leather incorporated in the tire prevents punctures but does not affect the natural resiliency of the tire.

This tire is made of combed Sea Island Cotton with the very highest grade rubber compounds that can be produced and is not only trouble-proof but is the most durable tire that can be made.

The Woodworth Trouble-Proof Tires when used with good tubes will not only give you perfect tire service but on account of the long mileage will cost less per mile to run than ordinary tires with their punctures and other troubles.

GUARANTEE

We guarantee Woodworth Trouble-Proof Tires to run 5,000 miles without punctures. If punctured, we agree that the purchaser may have both tire shoes and tubes repaired in a first-class manner and upon the bill being sent to us, we will immediately send our check in full payment, or if the purchaser prefers, he may send the punctured tire and tube to us express collect and we will repair them without charge and return them prepaid.

We also guarantee Woodworth Puncture-Proof Tires to outwear any other make of tire on the market. If when used under similar conditions on one side of the machine against any other make on the other side, they do not wear longer, except when destroyed by accident, we will refund 2½% of the purchase price for each 100 miles that they fall short of the mileage given by the other make.

LEATHER TIRE GOODS COMPANY

If you are willing to make a fair initial investment in tires in order to get perfect tire service which will ultimately result in economy, these are the tires you should use.

One or more tires tested as suggested in our guarantee will show you how you can have the best tire service in the future at the minimum of cost.

DRY BATTERIES.

Their Evolution and How They Can Be Made to Give Good Service.

BY SYDNEY F. WALKER, M. E.

No. 1.

Dry Batteries for Motor Cars.

In the following articles, the writer proposes to describe the evolution of the dry battery, and to show how it can be constructed to do quite as good service as the accumulator, both for lighting and for ignition. He proposes also to explain the principles on which the connections of dry batteries should be made to obtain large currents from them when desired, and their special construction when large currents or heavy work is required of them. He believes that the dry battery is very much misunderstood; that if properly constructed it would do a great deal of work that is now done by the accumulator. It goes without saying that it would be very much better and easier if a battery of cells could be carried upon a car, that would furnish current for lighting, for ignition, and for starting, in place of the accumulator, with all the requirements in the matter of charging. The accumulator has done very good work, and as it is being steadily improved, the

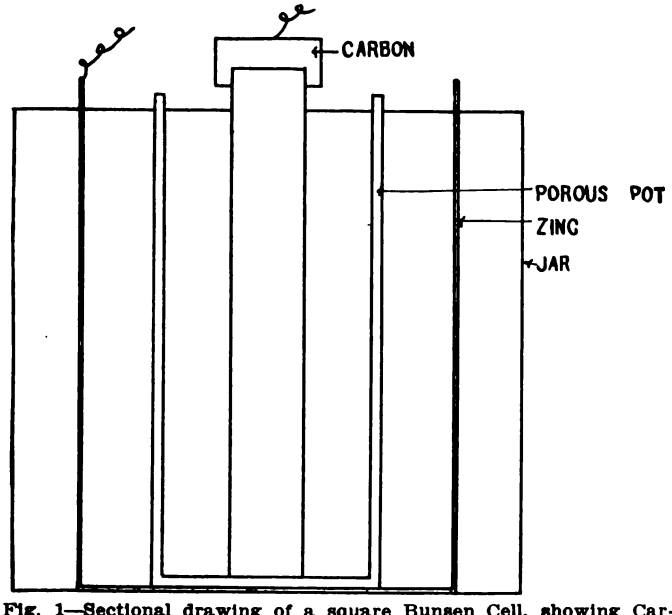

Fig. 1—Sectional drawing of a square Bunsen Cell, showing Carbon Plate, Porous Cell and Enclosing U-shaped Zinc.

work obtained from it is becoming better and better; but at the best it is an uncertain apparatus. At the best the problem involved in charging it from a dynamo carried upon the car is a troublesome one. There is always the chance of overcharging, and again of the accumulator discharging through the dynamo. Provision has been made against both of these contingencies, but the provision has involved a considerable amount of complication. It will be remembered that a "cut in" and "cut out" is necessary; and while modern apparatus for that purpose is remarkably good, there is always the possibility of the moving member of the apparatus sticking, either in contact, or out of it. Those who have employed accumulators will hardly need to be reminded of the troubles arising from their use.

On the other hand, if a battery can be carried on

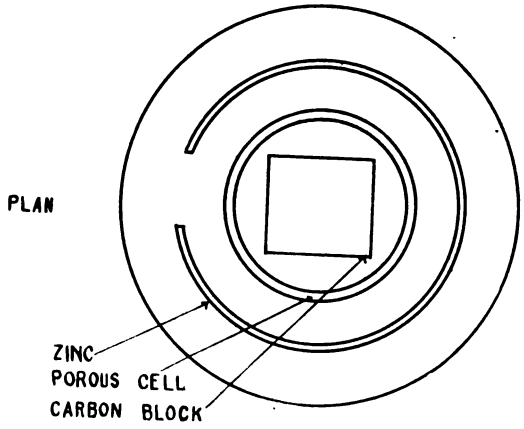

Fig. 2—Plan of Cylindrical form of Bunsen Cell, Showing Carbon Block, Porous Cell and Zinc Cylinder.

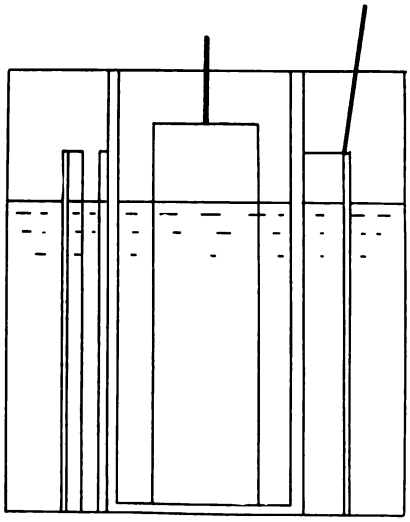
the car, that will displace the dynamo, and that will render unnecessary all the complicated apparatus in connection with the charging of the accumulator and the varying speed of the dynamo, even if the cost of renewing the batteries should be moderately high, the writer believes the cost would not be grudged; and that the whole arrangement would be superior to that of the dynamo and accumulator.



The dry battery, it will be remembered, was used to a considerable extent in the early days of the motor car, for the ignition outfit. It is still used to a large extent, but it has been gradually displaced by the accumulator, and particularly since cars are being lighted by electric lamps and the electric starter has made way. The reason for the dry battery falling into disuse, the present writer believes, is because the principles upon which it should have been constructed were not understood, and because a little extra weight upon the car was shirked.

The Evolution of the Dry Battery.

The dry battery has been evolved from the wet Le Clanché cell; it is practically a Le Clanché cell, in which the sloppy element has been discarded. The present writer has a very long experience with batteries of all kinds. A good many years ago he was responsible for the maintenance of a number of wet Le Clanché cells, and he was obliged to do the maintenance work himself, because the price obtainable for the work was such that the wages of a workman would have quickly swallowed it up. Naturally the performance of the work in connection with the maintenance of the batteries gave the writer an experience of Le Clanché batteries that

Digitized by Google

is not often obtained even by manufacturers or by men who are employed in looking after them. He repaired his Le Clanché batteries upon the ground where they were used, keeping material there for the purpose, and for the two or three years during which the maintenance contract lasted, he had the peculiar gratification of knowing that the maintenance cost was practically nil. The batteries used practically nothing, though they were hard worked as batteries went in those days. The only expense in-

ELEVATION

Fig. 2A—Sectional Elevation of Bunsen Cylindrical Cell.

volved was his train fare, and his personal expenses while going to the batteries. As the train fare took him into the district where further work was to be obtained, the whole arrangement was a very profitable one.

When after a few years, the usual thing happened, and the writer's business had so increased that he was not able to give the time necessary to looking after the batteries himself, he put a workman on for the purpose, and the maintenance revenue, which by that time had been increased by the addition of further batteries, was very quickly swallowed. Fortunately he had coached the officials where the batteries were in use, at collieries, how to look after them, and the contracts were closed.

Subsequently to that, the writer conducted a long investigation, and made a long series of tests, to ascertain exactly the conditions for the production of a cell that would stand. How far he was successful will be understood when he mentions the fact, that a good many years afterwards, some of his own cells were brought to him, that had been in use for 10 years, and were then practically as good, so far as giving a satisfactory current was concerned, as when they were made.

The currents which Le Clanché batteries of those days had to supply, were very much smaller than the currents that would be required for lights, or even for the ignition of say a 6 or 8 cylinder engine; but the principles upon which the batteries were constructed are the same, and in his opinion it is merely an extension of those principles, to enable batteries of sufficient capacity to be turned out to perform the work sketched above.

Earlier Batteries.

The Le Clanché battery came as a great boon to the electrical world of those days. Previous to the introduction of the Le Clanché battery, there had been a few forms of battery that could be employed for furnishing current, but none of them could be left for instance in a private house, to ring a bell, or to furnish a current for a telephone. If one wanted a powerful current to furnish an electric arc lamp a battery had to be employed. In those days it will be remembered, the arc lamp was still in the experimental stage. The writer has a vivid recollection of furnishing a battery for a lecturer, who was describing the arc lamp; and of the lecturer's remarking, that something which had required a cessation of the light illustrated the unreliability of the arc. The battery that was employed for that purpose was the Bunsen, which may be found described in text books, and which is illustrated in Figs. 1 and 2. The Bunsen battery employed zinc standing in a fairly strong solution of sulphuric acid, and carbon or platinum standing in a mixture of nitric and sulphuric acids. When the battery was at work, there were strong fumes of nitrous oxide gas coming away from the carbon cell. It will answer very well for a lecture experiment, but is uncertain even for that. One had to be very particular indeed about the connections between the zinc plates and the carbon or platinum plates. A loose clamp for instance would lead to sparking, and to trouble. The Bunsen battery of those days was looked upon as a thoroughly practical apparatus, inasmuch as the inventor of an electric motor designed to drive boats in the water, who informed the writer that he had driven a fairly large boat upon the River Neva, employed Bunsen batteries. His complaint was, not that the zinc was expensive, but that such a large quantity of acid

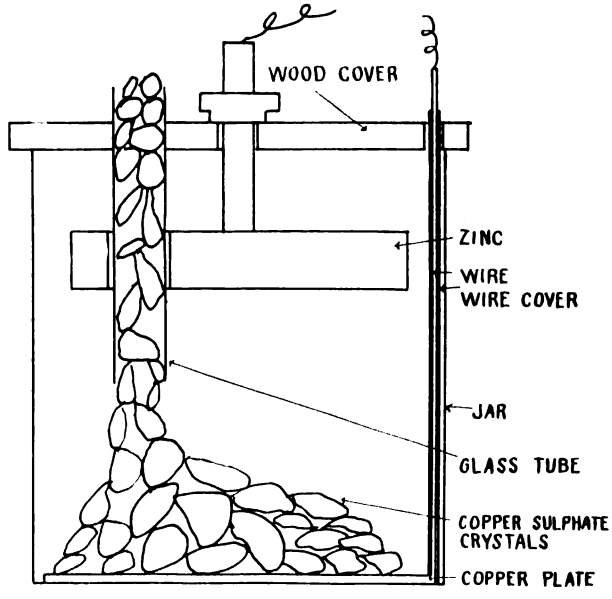


Fig. 3—Sectional Elevation of early form of gravity Daniell's Cell, showing zinc and copper plates with crystal of sulphate of copper on the bottom of the containing jar and in the glass tube leading to it.

was employed, and that the expense generally made it prohibitive. The writer understood that the inventor succeeded in keeping his batteries going fairly well and that he ran his boat for a fairly long distance. Obviously however they were useless for what may be termed commercial work.

The battery which had done the best service at that time was the Daniell. It was the invention of Prof. Daniell of Kings College, London, and was hailed at the time as a great discovery. Previously

Digitized by Google

to the invention of the Daniell and of Bunsen's batteries, it had not been possible to obtain a continuous current from a battery cell. Zinc and carbon plates, or zinc and platinum plates immersed in dilute sulphuric acid had been employed to furnish electric currents for a short time, but the appearance of hydrogen at the carbon or platinum plate had quickly broken the cell down. In the Daniell and Bunsen's batteries, the hydrogen was practically neutralized by the liquid in which the carbon or platinum plate was immersed.

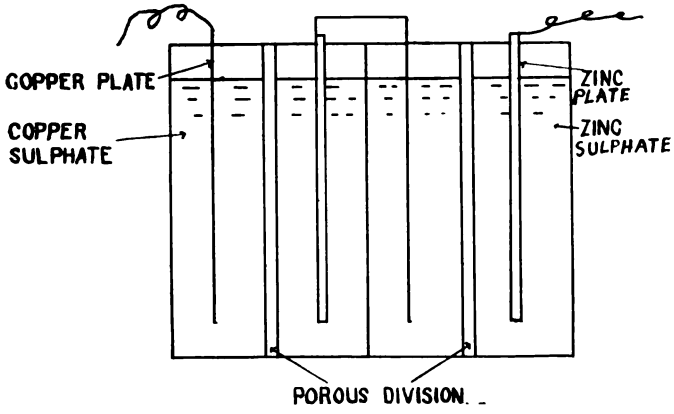

Fig. 4—Sectional Elevation of two cells of trough Daniell's Battery, showing zinc and copper plates and porous divisions.

Action of a Galvanic Battery.

Perhaps it will be as well before going further, to explain the action of a galvanic battery. It is exactly the same for the dry battery of the present day, as for the Daniell and Bunsen and Le Clanché battery of 30 years ago. The energy in every battery in which zinc is employed is furnished by the consumption of a certain quantity of zinc, proportional to the strength of the current passing. The zinc combines with the oxygen of the water in which it is immersed, and with the chlorine, or the acid radical $S O_4$ of sulphuric acid; zinc oxide, zinc chloride, and zinc sulphate being formed. The hydrogen gas which is liberated by the decomposition of the water, and of the salts that are dissolved in it, appears at the carbon or platinum plate; and it would there set up an opposing electrical pressure, unless it is got rid of in some way. In one of the early batteries, it was got rid of to a certain extent by roughened surfaces, platinum deposited upon silver, and a roughened carbon plate; but the result was not a very satisfactory one. In the Daniell battery, and in the Bunsen battery, the hydrogen was caused to decompose a substance placed around the negative element, as it was termed. As mentioned above, in the Bunsen battery, platinum or carbon might be used; in the Daniell battery copper was used. In the Bunsen battery, the nitric acid was decomposed by the hydrogen gas, new salts being formed, and the poisonous nitrous oxide mentioned above given off. In the Daniell battery the solution of sulphate of copper surrounded the copper plate, and the nascent hydrogen, as it was called, decomposed the sulphate, liberating pure copper, which was deposited upon the copper plate, sulphuric acid being formed, which was dissolved in the liquid. If a supply of sulphate of copper was kept in the neighborhood of the copper plate, and the current taken from the battery was not large, the pressure maintained by the battery was fairly constant; but there were a great many drawbacks to the battery. What electrical engineers call "polarization" took place. The action known by this name is also sometimes referred to as local action. The two solutions that in which the zinc plate was immersed, and that in which the copper plate was immersed, were separated by a porous diaphragm. In theory, the copper should have been deposited upon the copper plate and remained there; and the porous diaphragm should have remained porous. In practice it was found that a portion of the copper worked back through the porous diaphragm, some of it being deposited in its pores and some of it being deposited upon the zinc plate. Figs. 3 and 4 are two forms of Daniell's battery that had a great vogue in that time. In Fig. 3 the two solutions were divided by gravity. A copper plate laid on the bottom of the cell and was covered by a certain quantity of sulphate of copper. The zinc plate was in the form of an annular disc, supported from the top of the glass jar forming the containing vessel, by the lugs shown, which rested upon the jar. A glass tube passed down through the hole in the center of the zinc, the tube being kept full of crystals of sulphate of copper. Water was employed only in the solution. In the working of the battery, sulphate of zinc was formed in the upper portion of the cell, and a solution of sulphate of copper was provided in the lower portion. As the sulphate of copper was used up, the small crystals in the glass tube kept up the supply. This form of cell maintained a very constant pressure, though it could only be employed to furnish a very small current. It was very useful as a standard battery. In testing submarine telegraph cables, for instance, the standard pressure with which they were tested in those days, 100 volts, was maintained with fairly practical constancy.

The battery shown in Fig. 4, which was known as the trough Daniell, was employed for post office and railway telegraph work for a long time; and it was a number of years after the Le Clanché battery had quite established itself in work outside of post office and railway telegraphs, before the trough Daniell was displaced. In the trough Daniell battery, a wooden trough, made of teak, and lined thoroughly inside with marine glue, was divided into ten compartments by slate divisions. Each compartment was again divided by a porcelain diaphragm. Zinc and copper plates of the form shown in Fig. 5 were cast together. The copper plate was cut out of a fairly thin sheet copper, with a lug, and the zinc

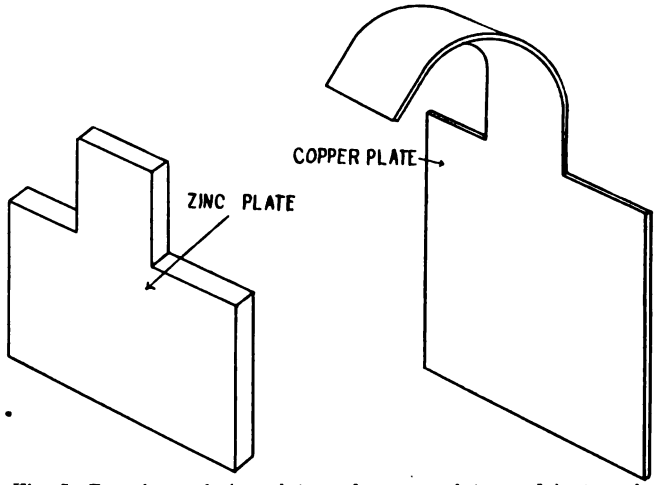

Fig. 5—Drawings of zinc plate and copper plate used in trough Daniell's Battery.

Digitized by Google

plate was cast round the lug. The zinc was subjected to a process called amalgamation; it was thoroughly cleaned with dilute sulphuric acid, and rubbed over with a coating of mercury. The pair of plates were bent round, as shown in Fig. 6, and were dropped into the battery, the lug being supported by the division between adjacent cells, the zinc being in one cell, and the copper in the next. Crystals of sulphate of copper were placed in the copper cell, and water only was used for charging them. In the process of working, zinc sulphate was formed in the zinc cell and sulphuric acid was formed in the copper cell, so that the internal resistance of the cell which was very high at the start, gradually decreased. There was the same trouble with this form of battery; the porous divisions were gradually filled up with deposited copper, and copper also was deposited in a very finely divided state upon the zinc plate. The deposit of copper upon the zinc plate caused what electrical engineers of those days again

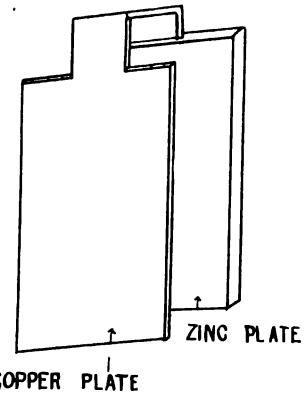

Fig. 6—Zinc and copper plates used for trough Daniell's battery ready for putting into the cells. The strip shown rests on the division between adjacent cells.

termed "polarization," and sometimes referred to as local action. What really happened was, the copper deposit and the zinc plate, together with the liquid held in the pores of the copper deposit, and upon the zinc plate generally, formed a local battery, which was always at work, and consequently the consumption of zinc was considerable; and also the local battery tended to reduce the useful current available. An army of battery men were employed by the railways and the post office to keep these batteries in order, but with a fair amount of attention they did their work very well. Battery men soon got to know how to keep their batteries going, by keeping the zincs clean, and keeping the copper plates whole. The copper plate tended to have holes eaten into it by another form of local action.

The writer has dwelt upon these points, as it will be seen later on, what an important bearing they have upon the action of the dry cell. All of the troubles mentioned above are to be found more or less in dry cells, and are to be guarded against by suitable arrangement.

(To be continued.)

Magnetos give a good spark when the engine is running fast, but for a hot spark when the engine is being turned over to start it the battery-delivered spark is usually the better. It gives even better sparks on slow than high speed, owing to better condenser action.

KEEPING TRACK OF THINGS.

Taking Stock, a Perpetual Inventory and Herding Pedestrians at Indianapolis, Ind.

BY JAMES F. HOBART, M. E.

Mr. Automobile Dealer, how much money have you got tied up in accessories, repair parts and other stock? Do you really know what you have stored away on those shelves? Do you know how many of each accessory you have in stock? Do you know how each thing sells, how they are moving, or whether they are moving at all or remain dead on your hands?

There's a tire pump in the window. How many of those pumps have you in stock? If you should have an order for two pumps right now, could you fill the order? Will you have to look around to see? It seems to me that such a way of selling and of keeping things for sale is not a very good way, especially when you might so arrange things that you could tell at any time, in thirty seconds, just how many tire pumps or anything else you have on hand, how many you are selling from month to month, when you bought the last lot, and you might also know when to order the next lot so as not to get out entirely and still not be overstocked.

Why don't you keep a "perpetual inventory" of your stock in trade, accessories, repair material, and everything you have to buy, use and sell? Then you will know at all times just how much you have on hand, when the supply went, when you ought to buy, and approximately how much will be sold during the year. The perpetual inventory will also enable you to weed out the non-sellers, and to push the things which are selling best.

I can't show up the whole system in this story, but I will try and tell enough about it so you can open a system in your garage and save yourself a whole lot of trouble by keeping perpetual tabs on what you are selling and carrying in stock. To begin with, it will require a little printing, a few loose leaf covers, and the establishment of some system of selling whereby a record is kept of what is sold.

It is pretty hard to even imagine a garage of today, without some system of accounting for the cash received and the stock delivered. Even the old-time day book, in which each and every transaction is entered is better than nothing, but a sales slip of some kind is still better, made out at the instant the sale is made. A pad of paper, carried in the pocket will answer, but almost any large stationer can supply cash slips similar to those used in some of the stores. And you can get them plain, or duplex with carbon slips, so that a duplicate may be given the customer if you wish.

There is another kind of cash slip which is very good for garage use. This is in a machine, permanently located at some convenient point and containing two rolls of paper with a carbon film passing between. A section of the paper, printed if you wish, is exposed through an opening in the machine and here the sale is recorded in pencil and the outer slip is fed out of the machine by turning a roll and this slip may be torn off and given to the customer. The carbon copy of the transaction remains in the machine from whence it may be removed at will for posting by the owner or by his bookkeeper. This system is pretty good. No slips are ever lost before they get to the office, but a loose pad is far better

Digitized by Google

than nothing, and will enable the perpetual inventory system to be operated.

The illustration herewith, shows a loose leaf from one very good form of perpetual inventory. This sheet is 6 in. x 9 in., a very convenient size and is ruled and punched as shown. The punching is for holding the sheet in loose-leaf holders. The ruling may be changed to suit the particular business of the garage man and he will have some ideas of his own as regards the ruling and the several headings after he has operated the system for a time.

Procure several of the loose-leaf holders, and also some files in which the leaves may be placed after they have been filled. Go over everything in the garage which is for sale, and sort out things and list them, then make out a leaf for each article in the garage which you wish to sell.

Fig. 1, shows a leaf made out for the tire pumps. We will not bother with those on hand, but assume that you are just ordering a new supply and that 12 came in on the sixth of October, 1914, and it is so entered upon the "In" columns of the slip. Next day, the 7th, the slip shows that two were sold but no more were disposed of until November 4th, and 6th, when one and two were sold. One more was sold on December 6th and two on the 19th. This completed the sales for the year and when inventory took place—that bug-a-boo of all stores and factories which do not keep a perpetual inventory, there was nothing to do but to add the number of tire pumps sold, subtract that number from the 12 purchased on Oct. 6, and "On Hand 4" can be entered under 1915, and the inventory is finished as far as tire pumps are concerned.

With one of these loose leaves for each and every article sold, or on hand, inventory is the matter of a few minutes with the book and there is no hunting over the contents of shelves, bins and drawers. All you have to do is to add two columns, subtract, and post the quantity on hand in its proper place. The value of this system depends of course, upon the accuracy with which sales are reported and entered as they occur. Without this, any system is valueless, and the slips turned in from sales must be entered in their proper place in the "out" column.

There is a whole lot more information upon the sheet concerning tire pumps. The name at the head of the sheet "Power Tire Pump" tells its own story. The next line, "Part No. —, Group No. —, Drawing No.—" is noticed when stock is purchased. Should you manufacture something, then this line will come into use.

The next line is very important. The "maximum" tells how many pumps you feel able to carry in stock. This is of course subject to change as the sales increase or decrease. The "minimum" tells when to order a new supply. This is also changed as the sales vary from year to year. The larger the number of sales, the longer the time required to obtain a new supply, the greater "minimum" number of pumps should be carried. The next two words, "Section and Bin," locate the storage place of the pumps in your stock room. These words may of course be changed to suit conditions, to shelf, drawer, box, etc.

Next comes a very important word: "Page 22." This refers only and entirely to the place occupied by the sheet in the loose-leaf binder. It means that there are 21 other sheets before this one, and when you replace this sheet with a new one in the book, you will number that one also "22" and place it between Nos. 21 and 22. And no matter how many of these loose leaves you use and fill, they will all be numbered "Page 22," for they will always be found at the same place in the loose-leaf book.

The next entry, "From sheet 3 to sheet 4," takes care of the sheets you fill out and remove from the book. The last sheet filled was No. 3, therefore this one will be No. 4 and after it has been filled out, it will be stored away in File No. 6, and a new "Page 22" will be put in the book in place of this one. The next line, "Plated or Unplated" does not amount to much for garage work. It was used by the concern

A Sample Loose-Leaf for Stock Keeping.

whose blank chanced to be reproduced as in the illustration.

The longer this system is in use, the more valuable it becomes. After you have operated it for two or three years, you can look back and see just how any article has sold—the number per year, the time of year when it is "slow" or when there is a good demand therefor and you can also predict what the probable business should be in that particular article during the next year or six months. This estimate must of course be modified largely by whether or not the times are "good" or "bad."

The filling in of the inventory sheets should be done at least daily. The sales slips are the material from which to post this side of the account. If you are doing some manufacturing, then you may need the column of "Stock" on the "out" side of the sheet. You may need this anyway, for if you equip an automobile which you have for sale, with one tire pump, then that pump should be marked up as put out to "stock." If you have a large enough shop to

Digitized by Google

warrant a store room and orders for material therefrom, then the column of "orders" and "remarks" will come into use. But if you have only a small place at present, the column of "orders" will get all the "outs" as it does in the illustration where a simple check mark is all that is needed to tell the story unless there be a numbered order in which case the order number goes into this column. And likewise, if you place a pump in "stock," then by all means place in that column something which will tell what car the pump was placed with. In this manner, you keep data which will be of great value in the future in case of disputed litigation, etc. It takes a very short time to post up the sales upon the sheets. You have no writing to do, only three figures to make, to record each sale and to tell the whole story.

One acquaintance of mine, who has only a small place, finds time to post the inventory slips as he looks over the sales slips for the day. He has a similar loose-leaf system for his sales, and when he posts that, he slips the figures into the inventory blanks also, and so never minds the slight labor called for by this system.

Another acquaintance with a little larger place who keeps a stenographer has her do all the posting. The slips go to her desk and she utilizes the odd moments for posting the inventory, the cash, and all the other necessary bookkeeping. In a still larger place, where there is need for a storekeeper, that official posts the inventory and he has so large a one that it fills 26 or 28 loose-leaf books and makes a shelf of books about 40 inches long. He keeps them in a sectional case on top of his desk and can reach any book easily. He posts the inventory sheets during his odd moments and says he never finds the system tiresome or requiring more time than he has to spare for it.

The "In" side of the sheet is of course filled from the bills and invoices all of which go through the hands of whoever holds the perpetual inventory books and from these bills and receipts, after they have been duly O. K.'d, the "In" side of the sheet is made up. The storekeeper, however, may make up the "In" column from the articles themselves as actually received at the storeroom. Each garage will quickly settle that question according to its own limiting conditions and surroundings. But let it be poorly kept, and the system is almost worthless and not worth the little time which is spent upon it. Faithfully kept, however, the system is worth many times the cost of its upkeep.

Herding Pedestrians.

The police of Indianapolis, Ind., have safely engineered through an ordinance whereby two "cops" instead of one will be stationed at each street intersection, and hereafter they will be autocrats of pedestrians as well as bosses of teams and automobiles. This means that pedestrians must obey the rules of traffic—as they should do—as well as horse drawn and self-propelled vehicles.

This is a much needed reform in Indianapolis—and in many other cities as well—for the manner in which pedestrians rush the street intersections at all times, is without right or reason. Henceforth, the "common people" must come under the yoke and obey common sense traffic rules as well as must automobiles and other vehicles. But it will require an awful lot of talking, cajoling, threatening and diplomatic action to educate them to the point where they will obey traffic rules without trying at each and every opportunity to break or evade those rules.

Women seem to be particularly aggressive in this respect. Probably the same intuitive instinct which leads them, one and all, to get off a street car backwards, is what makes them dodge across the street anywhere and everywhere, in defiance alike, of traffic rules and vehicle-crowded streets.

Why the Magneto or the Battery?

A paragraph in a recent issue of this journal stated that a better spark could be obtained from a magneto than from a spark coil when running at high speed, and that a better spark could be obtained from a coil when starting than from a magneto. This is a fact and automobile drivers will probably be interested in determining why such is the case?

Time is a necessary element in the operation of both magneto and spark coils and it requires a certain length of time for magnetic effects as well as electrical impulses to be transmitted from one point to another. True, the time required is very short indeed, but it is measurable.

In a spark coil, the ignition current is induced by lines of force which radiate, so to speak, from the primary wire or circuit. When contact is made and the primary circuit completed, the lines of force leap out and pass through the secondary winding, inducing a slight but comparatively feeble current in the secondary coils—feeble for the reason that the building up of the outgoing lines of magnetic force are rather gradual and cumulative. But still there is current enough induced in the secondary winding of the coil to give a small spark across the plug terminals, and should the timer permit, this wild current might cause ignition at a most undesirable time. Therefore see to it that the timer be so arranged that these "make" currents cannot get into any of the engine cylinders.

When the primary circuit is broken, the projected lines of force vanish—retreat if we may be allowed that expression—seemingly returning to or into the primary wire of the coil. They seem to return but they don't. They simply vanish. But, vanish as they may, their passage through the secondary winding of the coil causes a very strong impulse or current, which equalizes itself by leaping across the spark plug terminals. The quicker the break in the primary circuit, the greater will be the current in the secondary wiring and the fatter will be the spark.

It requires a certain length of time to push the magnetic lines out from around the primary wiring, to extend them through the secondary wiring and to return them again to the primary. Time must be given for the magnetic lines and the induced current to form, extend and retire. If the primary circuit is broken before the lines have fully extended themselves, they return and set up the second induced current in the secondary wiring before the first current has reached its full strength, therefore, like the baseball player who hit the ball and was thrown out before he reached first base and returned to the bench, we may express the movement of the current same as did the small boy who summed up the batter's movements as: "There goes Bill coming back!" Therefore, if we demand from the spark coil, impulses so rapidly that the coil does not

Digitized by Google

have time to fully charge and discharge itself between required sparks, then the strength of each spark will be necessarily reduced and the coil spark does not ignite well at extremely high speeds.

On the other hand, the magneto current is formed by the passage of the armature winding, through the lines of force which flow across the gaps between the field magnets and the armature core. There is no induction here from one current to lines of force and from lines of force to another current. The induction is, if you wish to call it that, directly from the lines of force to the current which leaps across the spark plugs.

The quicker the primary circuit breaks in the coil, the better the spark at the plugs. The quicker the passage of the armature winding through the magnetic field, the better the spark at the plugs, therefore the faster the magneto runs—within certain limits—the better the spark, and as there is very little danger of exceeding the "certain limit" within the speeds required for automobile ignition, the magneto must necessarily do better when the car is running fast while the coil does its best work while the car is running slow or is at rest. Hence the peculiar fitness of the spark coil for starting and the magneto for fast running.

There is a type of magneto on the market wherein the armature coil is "jerked" through the magnetic field between the permanent magnet poles by means of a sort of snap switch arrangement. This being the case, no matter how fast or how slow the car might be running, the passage of the exciting coils through lines of force is always the same and should the engine be moved far enough to work the "snap switch magneto," then an igniting impulse should be given as good and as strong as when the magneto was working at top speed. With satisfactory durable details, with which I am unacquainted at this writing, a magneto built upon this principle should go far toward solving the magneto problem of starting the car from a standstill equally well as a battery can do it.

ANOTHER GREAT HIGHWAY.

A National Road Connecting the Picturesque North and South.

From Felix J. Koch, Ohio.—Cincinnati—the logical gateway between North and South—it makes its way northward toward Hamilton and Dayton, then beyond, until it comes at last to its own end, somewhere on the Canadian border. Southward it extends through the very heart of Dixie, over the old Lexington turnpike, to Lexington, in the Blue Grass country, and then on and on and on to the bottommost south of the republic! It is to be to the North, and again to the South, what the Lincoln Highway means to the East and the West. Already the shippers are contemplating schedules for making best use of it, while the motorists are already arranging to go south the first opportunity, over this new National road.

And what a long, picturesque, delightful jaunt there is in store for him who has the time to tour from end to end of the Dixie Highway. What quaint, delightful sections, many of them well-nigh unknown to the great traveling, touring world, will come in review. What wealth of tobacco, what thoroughbred herbs, what bales of blue grass seed, what flocks of sheep, what hemp, and what other grains will be transported cheaper and faster, than ever before to rail or perhaps sail, as results of the new big road!

You who would "do" the Dixie Highway at its best plan your trip for the early fall—the summer end—when the tobacco cutting season is on. You'll

To the Manner Born.

do well to park your car at some garage near the splendid schoolhouse in Avondale, the aristocratic suburb of the Queen City, the night previous, setting the alarm clock for four, that you may be off with the lark and so come into the interior Kentucky towns at school time and meet with the picturesque pickaninnies. A duster, or raincoat, a cap, the lunch in the box, and you are prepared for as quaint a jaunt as any in all the land. Somewhere in the suburbs you will stop for a cup of hot coffee to warm you, for it is apt to be a trifle chill, before you are

The Wayside Judges.

actually under way. Through aristocratic Avondale, cosmopolitan Walnut Hills of the Queen City, then down into the heart of the city iteslf, the business heart of the town.

On the Esplanade, dozens of automobiles are already "parking." The owners come in over this south and north end of the Dixie Highway to do their day's business in town. Continue on toward the Ohio, and great herds of pigs are encountered, fresh off some river boat and on their way to the distant stockyards. Cincinnati is a "porkopolis"

Digitized by Google

still, and these big droves of pigs are seen by every stranger.

By and by you cross the suspension bridge, spanning the Ohio, and enter Kentucky and are in the real south. The toll for an automobile is but 15 cents on this bridge now, and just the view of the river, with the Queen City at the foot of her hills

Mostly Tobacco.

behind, and the five Kentucky cities ahead, is well worth what may be paid.

You enter Kentucky at Covington, the quaint old suburban town, and the comely old Kentucky court house detains you. The squirrels running around on the court house square as they did in old pioneer days.

Almost as old as the history of Kentucky is that Lexington turnpike. Nobody seems to know just when it was built. Jack Roosa seems to associate it with Henry Clay and the early pioneer times in Kentucky. To-day it is a mighty good road indeed.

Every so often signs give word of curves ahead

Stacking the Weed.

where automobiles slow down, thus insuring safety to all passers. Giant curves, in fact, are a feature, as you travel on. The road is oiled and good, the ascents are mild, so mild that sick folk who are taken down the road to Dry Ridge, a health resort, do not mind the journey at all. Now and then some old iron mile post punctuates the way while the shrill chirp of the crickets fall on the ear as you stop to snapshot.

Great asparagus farms put in appearance next. Truck, such as that will be shipped to advantage on the highway. Cattle graze in the orchards, spelling dairy products, and there is fruit traffic as well. Away off at the right a picturesque seminary, up on Price Hill, reminds one of Allen's tales of the Kentucky cloisters, as you catch sight of it through a gap. For dinner you choose Kentucky spring chicken, fresh Kentucky vegetables, preceded by a nip of Kentucky Bourbon, or a justly famous mint-julep.

By-and-by you begin getting a taste of interior Kentucky. The country slopes down from behind the hills, and broad fields of the tasseling corn, edged with the wild carrot and the ironweed, flank the way. Folk tell of side roads to Big Bone, where mastodon finds have been made. Then attention is turned to signs advising of frog fishing, and the broad estates of well-to-do Kentuckians, with summer homes of city folk, and the like. The children are gambolling beneath the trees, while some old darky mammy

Working on the Dixie Highway.

keeps watchful eyes, as she did on their sires before them.

The good, oiled road continues still. Garages offer gasoline at 12 to 13 cents a gallon, Signs come at intervals of each mile, giving the distance, and at one point a toll-gate bars the path with a fee of a nickel.

Soon the heavy foliage of the trees and the fields where the hay and the wheat are being harvested, attract the eye. A wee colt, following the mare, takes fright at the coming of the machine, and as you slow down you note how fine are these Kentucky horses.

Far as the eye can see, the tobacco fields extend, the plants standing very high and the leaves giving Roosa a chance to recall how last year 10 to 12 cents a pound was paid for them. You continue squarely ahead, and consulting your map, discover yourself traveling almost due south till you reach Dry Ridge, the "Spa" of this part of Kentucky.

Farmers, whom you meet, talk tobacco always. The plant grows like a weed down here. Good land for it will bring $85 an acre. Yonder is a single patch 220 acres, all in tobacco. Four old Kentucky farm houses rise from the fields. Little black children are going to school, taking their boxes of lunch

Digitized by Google

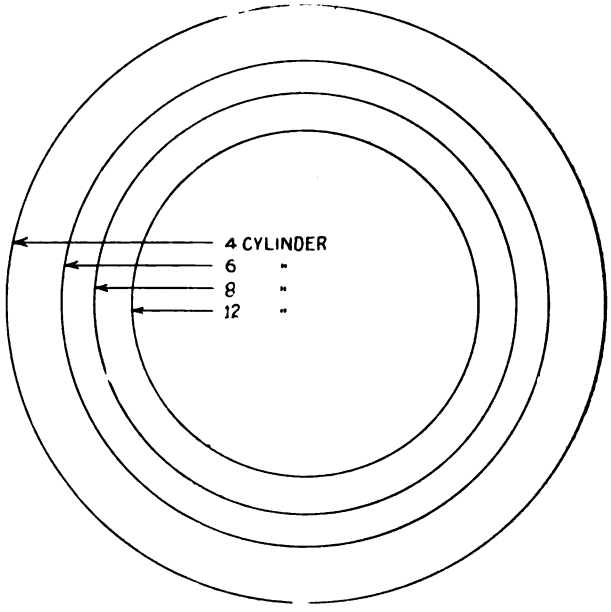
along, and you halt to snap their pictures. You note how the men here smoke all the time, this black native tobacco. You note how the osage enhedges the pike, with the wild anise beside. You remark then the great fields of timothy hay—a splendid crop—though it takes so much nourishment from the soil that clover in the end pays better in that it enriches the ground left behind.

Then, on and on you go, still into the heart of

Sunflowers and a Southern Peach.

Kentucky. Tobacco and blue grass choice stock, splendid thoroughbreds, fine old Kentucky estates, picturesque negroes, and this is but the beginning. From Lexington on into the deeper South goes the highway, opening up new sections, bringing new opportunity to old, vivifying and revivifying and promoting trade relations between neighbors, until it shall reach its goal in the bottom-most South; a long strip of progress, enterprise, life—a line of trade and of good communication to make stronger the ties between Northland and South.

CYLINDER MULTIPLICITY.



Is It to Increase to Twelve, or Will It Finally Go Back to Four?

The idea of a 12 cylinder motor is not to obtain greater power than in the four-cylinder model or the six-cylinder engine, but only to provide equal power, or even rather less power, though delivered with a much more even torque, with better balance, and better all-round running conditions.

So soon as one begins to enter the twelve-cylinder proposition, a line of doubt is encountered on a primary fact. How are we going to arrange our twelve cylinders? In one long line? Obviously not. In two groups of six á la the eight-cylinder engine? Possibly, it is rather an alluring proposition. How about three groups of four? Yes, that is feasible, as it makes such a short engine. Four groups of three cylinders any good? Well, that would entail lubrication difficulties, to mention merely one of several patent objections. Apparently, therefore, if we are going to have a twelve-cylinder engine, it is to be arranged either in two blocks of six cylinders á la the "eight"—but with the cylinders at 30 degrees from the vertical instead of 45 degrees, or else with four vertical cylinders, and four cylinders each side of the vertical group, at 30 degrees from the vertical.

Some Objections.

It would be quite a long technical treatise if we were to go into all the pros and cons of the two systems, but a few superficial objections may be cited against the three groups of four cylinders, sufficient to indicate a predilection in favor of the two sets of six. In the first place, then, with an engine in which three blocks of four cylinders were employed, carburetion would present a difficulty. Unless a strong case in favor of the adoption of three separate carburetors could be made out, one would hesitate to sanction their adoption as a move in the right direction. Two carburetors might be used, but the idea is not very sound. There remains the alternative method of one carburetor with a common mixing chamber. Under the ordinary system of suctional supply of gasoline, this is not very acceptable. Consequently, there is at once encountered a difficulty in an important matter like carburetion. From a constructional point of view there are also objections, and the designer who commences to lay

Size of Cylinders, 4, 6, 8 and 12 of the Same Rated Power.

out an engine on this principle soon finds that there are a number of designing difficulties to be overcome.

We will assume, then, that, if we are going to have a twelve-cylinder engine, it shall be built up in two sets of six cylinders. It now behooves us to see what advantages are obtained, and whether the twelve-cylinder proposition is likely to prove—in practice—sufficiently superior to the eight-cylinder engine, to become a practical proposition. If we take for an example a twelve-cylinder engine of, say, 30 h.p., and let it replace a six-cylinder motor of the same rated power, we see at once that we can save length. Of course, we are not going to save 50

Digitized by Google

per cent. in the length or anything approaching it, and we must not allow ourselves to fall into the childish—though still common—mistake of thinking that a cylinder of, say, 2 ins. diameter, is half as powerful as one of 4 ins. diameter. In order that the different cylinder diameters may be more easily comprehended, we reproduce a diagram which shows in comparison the diameter of a cylinder in a four-cylinder, six-cylinder, eight-cylinder, and twelve-cylinder engine of the same rated power. It is seen, however, if we judge for the moment length of engines by the ratio represented by cylinder diameter, that we get a considerable saving in the eight-cylinder design over a similar powered six, and a serviceable saving in a twelve-cylinder motor over a six-cylinder engine of the same power. This is shown adequately in another diagram which illustrates the saving in length obtained by the alternate choices under consideration when one goes beyond the standard four.

Now, although the twelve-cylinder design is certainly not so good from the length-saving point of view, it is equally certain that it constitutes an important improvement over the six-cylinder motor. In the vast majority of cars, as commonly purchased, excessive length in the bonnet is not desired either by manufacturer or purchaser. There are very few cars with long bonnets in which the harmony of outline does not suffer. Then, again, naturally one wants nearly all the total available "chassis room" for personal requirements as different from the mere housing of the motor. In this respect, then, we find that a good case is made out for the twelve-cylinder engine built in two pairs of sixes, although the writer—an eight-cylinder enthusiast—would draw attention once again to the fact that the "eight" is still better.

The Question of Torque.

With regard to the question of torque, one is bound to admit, of course, that the "twelve" would be better than the "eight." There are 50 per cent. more firing points, and that would naturally tend to improve the running considerably, although in regard to the actual torque diagram it is not easy to notice much difference in smoothness (on an ordinary scale) between the eight and the twelve. The length of the crankshaft in a twelve—even although it is so much shorter than what we are already accustomed to on a six—is a factor against it as compared with the eight. There is something very subtle about the long crankshaft which is necessary for a six-cylinder engine. In general terms one is bound to admit that the theoretical advantages of the six when compared with a four-cylinder engine do not materialize in practice by a long way. In fact, a capable critic is often hard pressed before he can admit any advantage in a six over an equally-made and similarly powered four.

As the twelve-in-two-sixes motor is new for motor purposes it is quite impossible to say how theory and practice will compare with regard to the advantages which a twelve possesses over an eight, on paper. The writer would not expect anything very pronounced in actual use. It might be that on the practice-theory ratio the twelve would show to better advantage than the six has done, but that would probably be all.

The twelve-cylinder is a more expensive manufacturing proposition, entails 33 per cent. more parts, such as pistons, connecting rods, valves, spark plugs and such like, and it is doubtful if it will give anything like a proportionate practical return. On ratio, it would certainly be more expensive to make than an eight. It would have a small advantage to some people's minds in being narrower than an eight, but the writer allows his eight enthusiasm to transmute this advantage into a disadvantage on the score of accessibility. If the eight is not too encumbered in the center, the valves are really quite get-at-able; if the cylinders are too close together (they are 30 degrees nearer in a twelve than in an eight) they would certainly become less accessible.

From the manufacturer's point of view, of course, public demand is the best incentive. Now, however, the Cadillac, Packard, Lozier and King have shown the way, and popular patronage has shown public approval, there are plenty who will follow, and this is rendered easy by the existence of so many specialist houses from whom engines of the new type can be purchased without the expense, trouble, and time necessary to get out new models of their own; in this case of the eight-cylinder engine, the matter is rendered the easier by reason of the fact that so large a number of firms are building six-cylinder cars, and the interchange of an eight-cylinder motor for a six entails no other alteration of the chassis; whilst in many cases where engines of equal power are in question, the smaller bore of the eight renders it possible for it to replace even the four without any chassis elongation being required. This peculiarity, too, presents rather an attractive feature from the point of view of the private owner, who, by changing his engine only, can, if he be enamoured of the new idea, indulge his fancy at a moderate cost without having necessarily to buy a new car.

The expense of making the alteration, either to the manufacturer who buys his engines or to the private owner who desires to make the change, is by no means excessive, if no chassis alteration is required to accommodate the new outfit.

BUYING A SECOND-HAND CAR.

You Can Get a Good Bargain If You Are Careful and Watch Your Chance.

On occasion one may pick up a particularly good bargain in a second-hand car. As with most other things, however, it is necessary to wait the opportunity. Speaking in general terms, the exceptional bargains are not to be obtained by walking into a dealer's to make a purchase. At the same time, at many of the leading second-hand dealers one can generally obtain good value for money in the second-hand car line but to obtain a good bargain with any degree of certainty, one must "know the ropes." As a matter of fact, few of the so-called experts know much more, or do much more when examining a second-hand car, than a reasonably capable amateur motorist. There are, of course, exceptions; men who possess years of greatly varied road experience, who know off by heart the precise points of weakness in almost every car—and every model of every car—on the market. These people, however, are very few, and can be counted on the fingers of half a hand, so to speak. How, then, is the motorist who wants to purchase a second-hand car to proceed?

One may buy a second-hand car from almost any-

Digitized by Google

thing up to $3,000, or even more. If one is spending from, say from $300 to $700 on a fairly modern second-hand car of known make, one might be tempted, after a trial run of reasonable proportions, "to take pot luck," although if the latter sum is to be expended, then undoubtedly obtain the services of one of the few real experts—not one of the alleged experts.

In some cases, of course, the man who is only spending a comparatively small sum, may be well

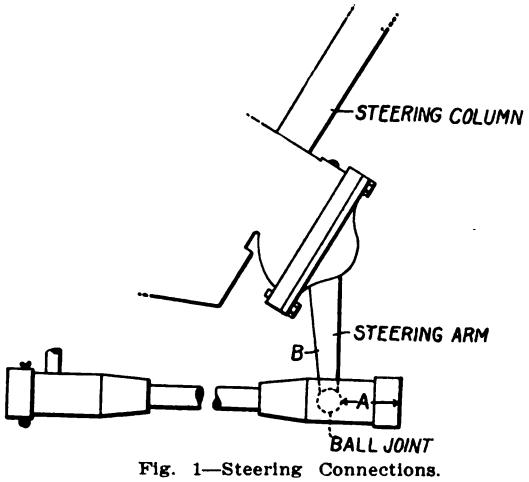


Fig. 1—Steering Connections.

advised to spend an extra $10 or so, if he gets hold of the real expert. Assuming, however, that no expert is to be engaged, how is the motorist to look the automobile horse in the mouth?

It is a broad and difficult subject. I must therefore condense the subject, and, by picking out a few of the inside "tricks of the trade" in addition to the common-place generalities of an automobile examination, hope to illustrate the way the intending purchaser should proceed. We will start with some generalities first.

Never worry much about the body. If there is a body there at all, and it is sound, the condition of the paint is largely a detail. Do not be put off by the appearance of the paint. Many a good bargain has been missed through first appearance impressions. The purchaser comes in and sees, perhaps, a very dirty-looking car, and, with a passing glance, says: "Oh! I couldn't have that." Nine times out of ten the salesman says: "Oh! no. Here's a much better one," quite irrespective of the fact as to whether it is or no. However, the car thus summarily dismissed might be an exceptional bargain as regards the chassis—and $25 (spent at the right place) would make a marvelous difference to the body work. Make straight for the chassis, then. First of all, make a general semi-cursory examination of the whole chassis, so as to formulate a rough idea of its condition.

If it appears that it might suit, then the examination must be carried a little further. Have a careful look at all the wheels. Jack them up one at a time and see if they "hang." Naturally they will—in the real meaning of the word. The technical meaning, however, is the difference between sound and worn bearings. If you can lift the wheel at all, if there is any vertical movement to be obtained without a corresponding lift for the stub axle, then the bearings are badly worn. If there is only a "shake," they are not as they should be.

Now try for lateral movement, and note carefully whether it is pure lateral movement or part vertical; that is to say, a tipping action in conjunction with the lateral movement. The latter is the worse, and means greater repairing expense.

Wheel Alignment.

It is also necessary to note whether or no the front wheels are in proper alignment. If they are not, of course they will have to be; and then comes the question as to whether or no the tie-rod coupling is adjustable. If it is not, and the eyebolts are worn badly, then they will have to be rebushed. An item in connection with the wheels which is frequently overlooked is the condition of the nave plates and spokes. If the wheels are of wood or steel, note whether the nave plates are still securely fastened and whether any of the felloes are loose. A loosely-built wheel is likely to break under a severe skidding strain. See that none of the spokes are cracked, and, finally, see if the wheel spins truly, apart from any bearing wear.

If wire wheels are fitted, study the condition of the nipples, and see that none of the spokes are broken. With regard to the rear wheels, it is, of course, most important to watch for play on the driving square or spline. With experience, one can learn a lot from the study of the road wheels, as they constitute to the trained examiner a sort of stethoscope, which leads to a fairly sound general diagnosis of the all-round condition of the car.

If the road wheels are in a bad condition, one may usually argue that the rest of the chassis will not be particularly good. One must not, however, al-

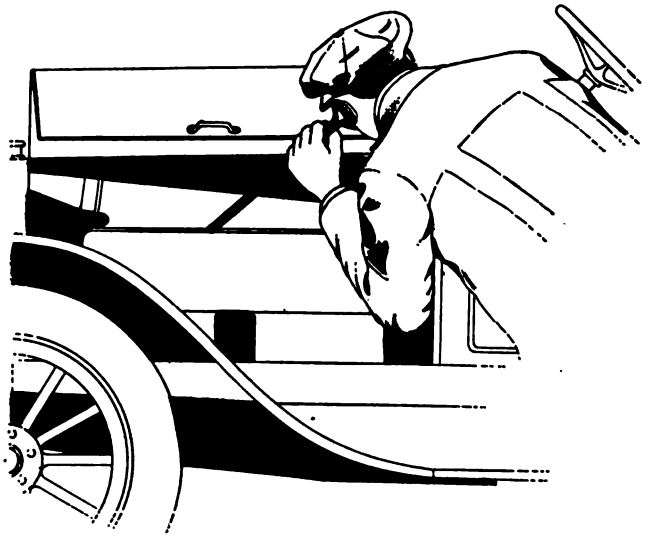

Fig. 2—Using a Stethoscope.

ways argue conversely, especially with wire wheels as they appear to stand an enormous amount of general ill-treatment without themselves exhibiting anything to indicate it.

The Steering Gear.

The steering gear may be taken next. See first of all if the steering gear box is loose in its attachment to the framework. It is advisable to take this point first, as it naturally affects other points. In modern cars it is not likely that much will be amiss with the anchorage of the box, but one finds it loose far more frequently than would be anticipated. Then there is the question of the amount of wear on the worm and wheel or segment, as the case may

Digitized by Google

be. It is very difficult to estimate the amount of wear in an encased worm, but for the steering one can usually form a pretty shrewd idea. Some steering boxes are provided with adjustments, and in certain cases the worm wheel can be turned round a little so as to bring the major portion of the work on to new faces.

Then there are the steering connections, rods and eye-bolts. A careful examination must be made of the ball joints, A, Fig. 1, especially on the steering arm, B, and also of the retaining socket nut. As so much depends on the steering gear, one cannot well be too careful in the examination.

The Engine Running Test.

In continuing our general examination, it is now necessary to come to the study of some of the other units. A preliminary opinion of the engine may be formed from running it and applying a stethoscope, Fig. 2. A well-trained motorist, if gifted with the mechanical instinct, can learn quite an appreciable amount as to the condition of the engine merely by listening to its running. If the engine seems in fair condition, leave it at that for the moment and tackle the gear-box.

The Gear-Box Examination.

One needs considerable experience in order to pass a reliable opinion on the gear-box. Of course some defects are palpable. For instance, the teeth of the second or third gear-wheel on the secondary shaft may be badly damaged. They are shown at A, Fig. 3. If so, it is by no means easy accurately to estimate their probable life, if it is not desired to replace them at once. Then, if other things are considered all right, and it is deemed advisable to replace the damaged gear-wheel, it is necessary to note the construction of the shaft. The more recently produced cars have usually got the gear-wheels separately mounted on the shaft, so that a new one can easily be put into position. However, it is common foreign practice to have the layshaft a solid unit. If so, replacing one gear-wheel means replacing the lot, which, of course, is an expensive item. This question of a worn gear-wheel constitutes a good example of the prior knowledge which a real expert should have, so as quickly to locate the places where money has to be expended. The defective

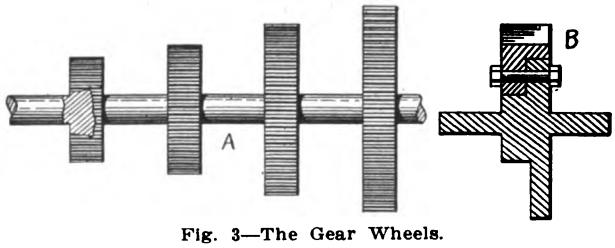

Fig. 3—The Gear Wheels.

gear-wheel is quite a common failing, and on one well-known make suffers badly from this defect. Yet it remains a secret from the ordinary buying public, chiefly because the construction is such that the repair is quite a cheap one.

A more difficult defect to trace is the bent gear-shaft which may lead to all sorts of troubles and noises. Then, again, it has to be noted that the gear-wheels are not too loose a fit on their splines or the square, as the case may be. There is also the question of the bearings, which is a fairly easy matter to settle, though the cost of renewal varies considerably with different methods of building the gear-box. Often the most palpable defects of all are overlooked in regard to the gear-box. I refer to the carrier arms, which must be cleaned and examined for cracks. The mere presence of a crack does not necessarily mean anything serious. It all depends on the nature and "lie" of the crack, though the art of differentiating between a dangerous and a safe crack rather baffles verbal description. I also always make a point of cleaning the base of the box and having a look round. One never knows. I once found a fairly large and neatly wood-bunged hole just near the bottom of a crankcase. The owner

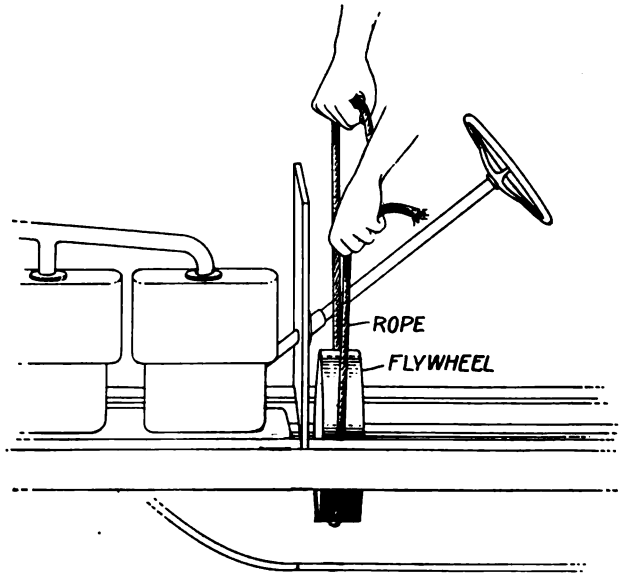

Fig. 4—Testing Crankshaft Bearings.

professed ignorance of this extraordinary repair, and, from all accounts, he was a man whose word could be relied upon implicitly. Goodness only knows how long that weird repair had been doing duty. So much for the gearbox: we will now, turn to the engine.

Examination of the Engine.

Either the engine is in good condition or it is not. It is a very difficult matter to arrange for it to be in temporarily good condition, as an unscrupulous person can do with other portions of the chassis. Of course, the most obvious defects are play in the crankshaft bearings or big-end bearings and knock. The former is, of course, easily traced, but it is not so simple a matter to differentiate between a knock that matters and one that does not; in other words, between a gudgeon pin knock and a carbon one. If the latter is only slight, it can be removed at very little cost, but a gudgeon pin knock means a considerable repair bill. Crankshaft bearings can usually be adjusted fairly easily, so that a little play does not amount to a very serious item in this respect. Standing astride the chassis, one can put a piece of rope round the flywheel, and, if fairly strong, can feel any play in the end bearing by trying to lift the flywheel up, as shown at Fig. 4. It is usually safe to assume that the other crankshaft bearings will not be in a worse condition than the rear bearing.

With regard to the big-ends, one can usually detect any play in these by listening with a stethoscope (often even without) for a little "ping" on the reverse kick as the engine is stopping after being

Digitized by Google

switched off. The engine should be fairly warm at the time the test is made.

The Water Jacket.

There are, however, some more subtle defects which should be looked for in an engine. Take, for instance, the question of a cracked water jacket. If this is external it can usually be detected by showing a thin rusty line. Even if this has been cleaned off, an outside crack should be revealed by careful scrutiny. If the metal should be porous anywhere, such defect is usually made noticeable by a little moist patch as the engine is warming up. When starting the engine from cold, notice if there is any undue amount of water or moisture from the exhaust pipe. If there is it is often indicative of an internal crack or porosity, probably adjacent to the valve pocket.

The Valves.

Another thing to which attention should be given in regard to the engine is the condition of the valve guides. Sometimes—especially on certain cars—these wear very badly, and in some cases the work of replacement is by no means so simple as it should be. On most modern cars, however, this is not a very serious item, and in most cases the guides wear much better than they used to.

The Flywheel.

It is now advisable to examine the flywheel. Here, again, the more recent design of flange coupling is not likely to have worked loose, but it is always advisable to have a look. The cone joint, which many people are inclined to jeer at, is—when properly designed—usually found to be in perfectly good condition.

The Clutch.

Disc clutches are not so easy to appraise, but actual road test usually gives one a pretty good in-

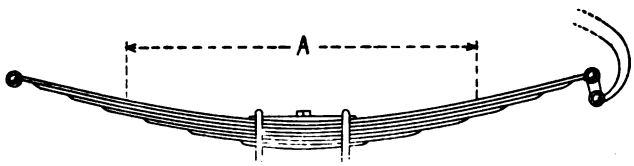

Fig. 5—Half Elliptic Spring. See that the leaves from the dotted lines, A, are broad and thin, not narrow and thick.

sight into the state of health of the clutch. Then come the universal joints, and if these are not found to be fairly well worn, it is the exception rather than the rule. Here, again, construction is an important factor. In some cars if the wear is very bad they can easily be replaced. In others, perhaps the whole back axle has to come down as well. With regard to the back axle, this is a difficult patient for the automobile doctors to diganose. One cannot really say anything very definite in many cases without dismantling the whole affair. Take, for instance, the case of the worm. An opinion may be formulated from road test and observation, but one cannot really tell. In one case on taking down a back axle the differential cage was found in halves! Yet the car had been running perfectly, and no one knew there was anything the matter. If it is possible to examine the differential through an opening in the casing, of course do so.

Examination of Details.

I must draw attention to one or two other points often overlooked. As an example, take the question of a differential brake. If it is badly worn, it only seems a small item to reline it. Yet there are cars on the market on which, before the brake can be relined, half the chassis has to come down. It is just a question of accessibility. The possibility of the chassis itself being cracked must always be borne in mind, and a diligent search should be made. It is rather more likely to be in the center—if anywhere—but by no means sure to be there. Another important point is the condition of the shackle pins. Recent design usually provides a hot-riveted dumb-iron, but many cars have not a separate dumb-iron. If the hole is badly worn, it must be drilled out and rebushed. Rebushing takes metal: see that there is enough left for the work to be done.

Then you must take a sharp look at the springs. See that they are intact, or if they have been mended, note how it was done. As for other and minor accessories, including the ignition system, examine them carefully, and find out whether or not they are of late and standard style. It is true, the replacement of some of them will not be of prohibitive cost but in any event you should know exactly what you are purchasing.

MOTOR STARTERS.

Some of the More Simple and Easier Systems for the Novice to Understand.

BY C. P. SHATTUCK, M. E.

No. 2.

The methods of imparting the energy of the electric motor starter to the engine vary as does the means utilized for obtaining the required reduction between the driving and driven unit. As it is not practical for the armature shaft of the motor to rotate at the same rate of speed as that of the crankshaft of the engine, in that it would necessitate a powerful and bulky unit, a reduction between the driving and driven members is employed. The ratio of reduction, as previously explained, is about 3 to 1, although it varies according to the unit and method of installation.

The operation of an electric motor starter is generally understood as a device that electrically rotates the crankshaft of the engine when a pedal is de-

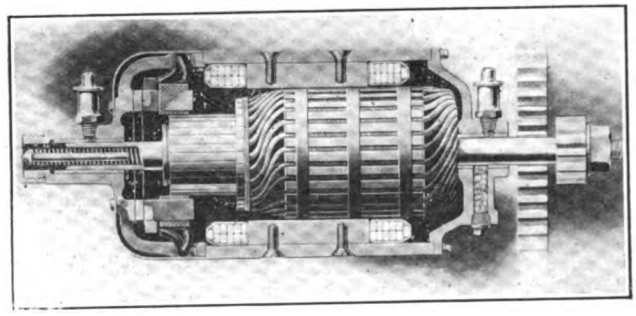

Fig. 14—Bosch-Rushmore starting motor showing sliding armature which moves to the left engaging pinion.

pressed, a button pressed or a switch is closed. This may apply in some installations but not in all for there is more or less mechanical movement in the operation of the starter, and the control and operation of the engaging or shifting mechanism is one of the several interesting features of electric motor starters.

The most simple and easiest form for the novice to grasp is the mechanical pinion shift which is largely employed. With it the energy of the bat-

Digitized by Google

tery is transmitted to the motor, causing the armature to revolve. This energy is transmitted through a pinion on the armature shaft to the flywheel, causing the last named member to rotate. The pinion of the starting motor is shifted into mesh with the flywheel gear on starting, and when the engine operates under its own power the pinion is shifted out of engagement. It is accomplished mechanically by a pedal or lever, automatically by a worm shaft mechanism, or electro-magnetically by a combination of electrically operated switch and pinion shift. These methods are employed with the single unit types. No pinion shifting is used with the two-unit types, the motor-generator.

The mechanical or non-automatic pinion shift will be easily understood by referring to the diagrams shown at Fig. 19 which illustrates the operation of the Westinghouse starter. A starting pedal is employed but the system can be operated or controlled by a hand lever. The drawing at A shows the neutral or "off" position of the switch contactor and the shift pinion. This condition exists previous to starting the engine and when it is operating under its own power. When pressure is applied to the starting pedal the latter moves the shift rod first to the position shown at B, closing the motor circuit at P and Pl through the resistance R. The current flows from the battery to the motor causing the armature to turn slowly.

A further movement or depression of the starting pedal moves the shift rod to the position shown at C, opening the circuit, but the pinion continues to rotate slowly due to its inertia or momentum. This permits the pinion to mesh with the flywheel, and upon an engagement being effected the starting pedal is fully depressed causing the shift rod to assume the position shown at D. At the same time

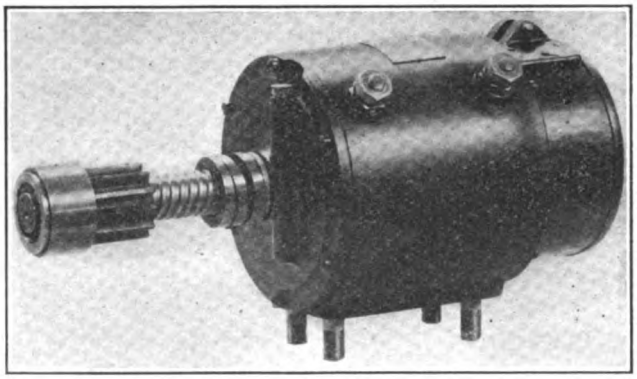

Fig. 15—Remy inertia pinion automatically engaging and disengaging with flywheel.

the electric circuit at Q is closed. This does not take place until the pinion and gear are fully meshed. The engine is cranked until the starting pedal is released or the engine operates under its own power. The Westinghouse system includes an over-running clutch incorporated between the pinion and the motor. Its function is to prevent the engine driving the motor if the starting pedal be not released properly. When the pressure is removed from the pedal, the shifting rod springs return the components to the position shown at A, which shows all gears disengaged and the circuit open. The travel of the switch rod is 3/16 inch for auxiliary contact, ½ for auxiliary contacts open, 9/16 for gears starting to mesh, 1¼ for main contacts and 1⅜ main contacts compressed. In some installations the switch is not mounted directly on the shift rod but is on a separate rod which acts on the gear shift rod by some form of lever.

Motor-Generator Types.

The Delco motor-generator, which is constructed to meet the requirements of different engines, is shown at Fig. 22, and employs a motor clutch operating between the pinion of the armature and fly-

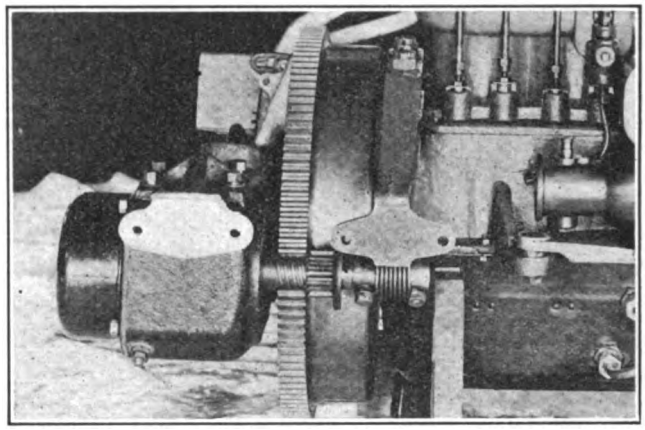

Fig. 16—Bendix drive employed with starting motor on Chevrolet car.

wheel for obtaining a suitable reduction between these members. It also serves to prevent the armature being driven at high speeds during the brief time the gears are in engagement after the engine is operating under its own energy. There is also a generator clutch which permits of rotating the armature shaft at a higher rate of speed than that of the pump shaft during the cranking operation, and at the same time the construction permits the armature shaft to be driven by the pump shaft when the engine is operating.

Both the motor and generator brush switches are operated by the pull rod E which also operates the starting gear. When the magneto or battery button on, the combination switch is pulled out, the circuit between the generator and cells is closed, allowing current to flow through the generator windings, causing the armature to rotate slowly. Depressing the starting pedal actuates the pull rod E which in turn meshes the gear J with the motor pinion, causing the motor clutch to rotate slowly. As the pedal is depressed or pushed further out the gear G meshes with the teeth on the periphery of the flywheel. With the complete engagement of the gears the pull rod E raises the lower generator brush, breaking contact with the commutator. Upon the pull rod E being moved sufficiently by the starting pedal to bring about complete engagement of the gears, it allows the motor brush to contact with the commutator, completing the cranking circuit.

Automatic Pinion Shift.

Starting motors of the single-unit type are sometimes provided with an automatic screw pinion shift such as shown at Figs. 20 and 16. The armature shaft of the motor has a specially threaded shaft which automatically shifts the pinion into mesh with the flywheel when the starting switch is closed. The switch may be operated by the hand or foot or be electro-magnetically operated, and with the last named the circuit may be closed by a push button type of switch located on the dashboard or steering

Digitized by Google

wheel. The operation is illustrated at A and B, Fig. 20.

When the starting switch is closed the full voltage of the battery is impressed on the motor, it starting immediately. When the motor is inoperative the pinion is within the screw shift housing and not in contact with the flywheel. The threaded shaft is connected to the reduction gear shaft by a spring which serves as a flexible coupling. As the load is not sufficient to compress the spring upon the motor

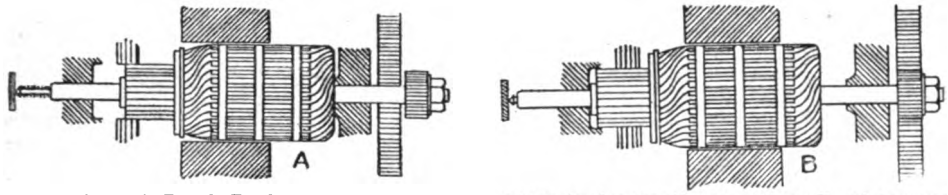

Fig. 17—Illustrating operation of Bosch-Rushmore starter: A, armature in inoperative position; B, pinion meshed with flywheel gear.

starting, the shaft is rotated by the spring in released position. The pinion moves out on its shaft because of the movement or momentum imparted by the rotating threads, and this energy is applied until the pinion reaches the flywheel. If the teeth of the pinion and flywheel meet, that is, are not in a position permitting of engagement, the spring permits the pinion to revolve until a favorable position for engagement is attained. Upon the pinion meshing fully with the flywheel, the spring compresses, and the pinion is rotated by the motor as through a con-

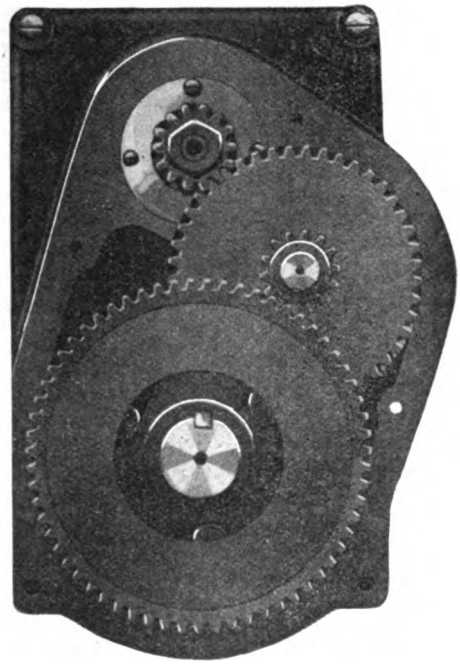

Fig. 18—Reduction gears and over-running clutch of Remy motor-generator.

tinuous shaft. Upon the engine operating under its own power and when the flywheel peripheral speed continually exceeds that of the driving pinion, it forces the pinion out of mesh. The pinion is returned to its neutral or normal position in the screw shaft housing. During the periods immediately after the pistons of the engine have passed beyond any one of the points of the maximum compression, the spring acts as an elastic cushion between the flywheel and reduction gear so that the pinion will not be thrown out of mesh.

The Bendix type of drive is shown installed on a Chevrolet motor at Fig. 16 and as may be noted the necessary reduction between the pinion and flywheel gear is provided by the difference in the size of the driving and driven member. The type of Bendix commonly used consists of a pinion mounted on a helical shaft extension of the armature shaft. Attached to the pinion gear is a disc with a weight on one side. When the starting switch is closed the helical shaft revolves but the inertia of the disc tends to hold the pinion stationary, preventing it from revolving too freely with the shaft. The gear is drawn in by the helical shaft until it is fully meshed with the teeth in the flywheel. Upon the engine starting and running, the tendency of the engine to drive the motor results in unscrewing the pinion on the shaft and disengaging it. Fig. 15 illus-

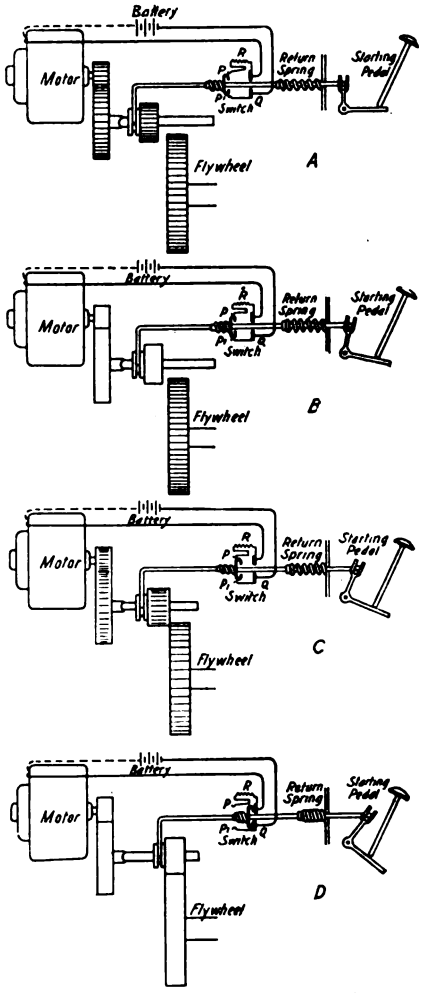

Fig. 19—Electrical and mechanical connections of motor and switch of non-automatic pinion shift, flywheel drive of Westinghouse starter.

trates the Remy inertia pinion, which is of the type that automatically engages and disengages with the flywheel type of drive.

Bosch Flywheel Motor.

The Bosch flywheel starter (system Rushmore) is shown at Fig. 14 and the principles of operation

Digitized by Google

are illustrated at Fig. 17. A pinion on the armature shaft of the motor engages with the flywheel. The gear ring may be mounted on the outside or inside periphery of the flywheel. The Bosch starter differs from the designs discussed, in that in the engagement and disengagement of the pinion the entire armature shafts moves. The operation is entirely automatic and is accomplished electrically.

By referring to Fig. 14, which is a longitudinal sectional view of the starter, it may be noted that the armature is so arranged that it can be shifted endwise on its bearings, parallel to its axis. In the normal position, as shown at Fig. 14 and A Fig. 17, the armature is held out of electrical center or out of line with the pole pieces by the tension of a spiral spring in the commutator end of the shaft.

Three cables or wires are utilized in the connections. The positive and negative leads from the battery are larger than the third wire, and one of these leads, the positive, is directly connected to the motor. The other battery wire is attached to the starting switch. A wire leads from an arm of the switch to the motor, and a third and lighter wire, the shunt, also connects the switch with the motor. Upon depressing the switch pedal the current from the battery first passes through the field windings of the motor, after which it is diverted both through the shunt wire and armature of the motor. The passage of the current causes the field coils to become a strong solenoid, its attraction causing a longitudinal movement of the armature, which when in its normal position is out of electrical center. Upon the armature being drawn into a working position the motor functions as a series wound unit. The driving pinion is meshed with the flywheel when the armature is electrically moved to the left, and in the movement an easy and complete engagement of the gears is obtained.

Upon the engine starting to operate under its own power the load is reduced and the current consumption decreases to a point where the magnetic pull of the field coils is overcome by the tension of the spring of the armature shaft, causing the armature and pinion to return to its normal position.

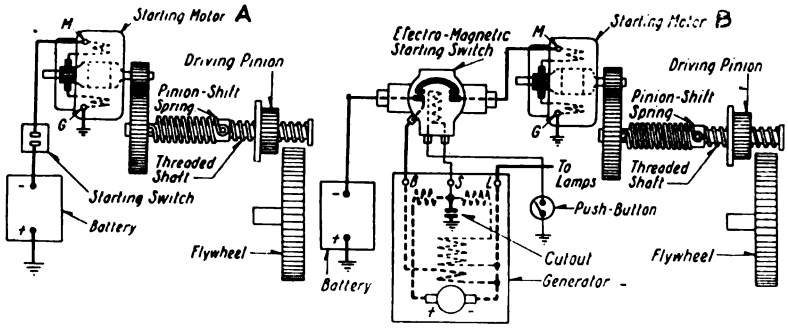

Fig. 20—Westinghouse double reduction automatic screw pinion shift and electro-magnetically operated starting switch.

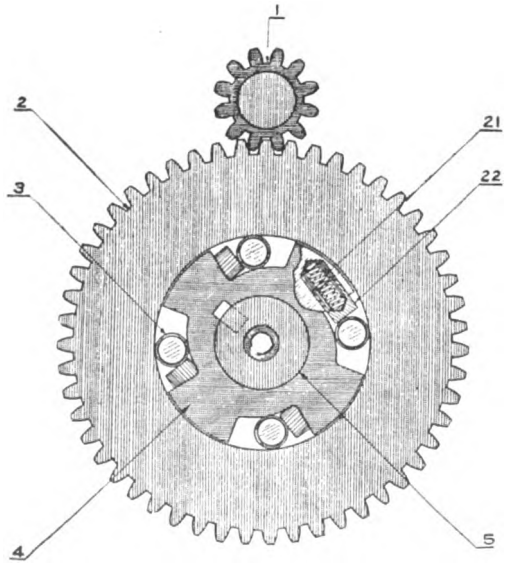

Fig. 21—Components of Gray & Davis over-running clutch.

Reference has been made to the over-running clutch utilized with the motor starter. When employed with the motor-generator utilizing reduction gears as with the Remy starter shown at Fig. 18, it disengages the motor armature and reduction gears which remain inactive when the engine is started and operating under its own power. The over-running clutch employed with the Gray & Davis starter is illustrated at Fig. 21, with its components numbered. It practically provides a connection between the starting motor and the engine when the starting pedal is depressed or operated. In installations where the motor starter is mounted forward of the flywheel, the motor rotates anti-clockwise, facing the driving end. The clutch then operates as follows: When the starting motor pinion 1 is rotated in an anti-clockwise direction, the intermediate gear 2 rotates clockwise, the rolls, 3, turn into the wedge angles between the curved surface of the clutch center 4 and the inner surface of the intermediate gear 2, with increased pressure until the friction is sufficient to drive the intermediate shaft 5 which is keyed to the clutch center 4. The springs 21, back of the plungers 22, keep the rolls 3 firmly within the wedge angles so that they grip as soon as

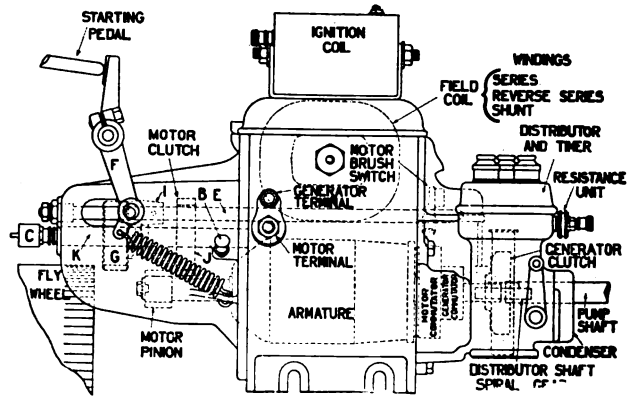

Fig. 22—The Delco motor-generator as installed on the Buick car.

Digitized by Google

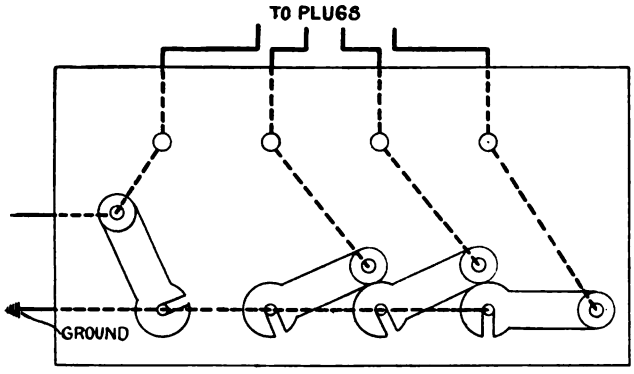
the motor operates. When the engine operates at a higher rate of speed than the motor, the rolls are released from the wedge angles, obtaining the over-running action of the clutch, thereby preventing the engine driving the motor. Over-running clutches are employed when a chain is utilized to impart the energy of the motor to the engine. A form of planetary transmission, similar in principle to that utilized on motor cars for obtaining changes of speed, is employed in the Wagner motor-generator. The gears are in engagement when the unit functions as a starter, but are locked together by three rollers in a star-shaped clutch when the unit functions as a dynamo or generator. The switch lever operates a brake band in the same manner as the planetary transmission is operated, the band holding the gear box stationary.

(To be continued.)

DEFENDS THE TWO-CYCLE.

And All Are Willing to Sit at the Feet of the Dean of Automobile Engineers and Listen.

From Chas. E. Duryea, Pennsylvania.—Your reply to No. 1588, while correct does not contain the whole truth. I look for the 2-cycle to win as an auto engine in time, but it will be much hindered if the public do not learn the facts about it and so I wish to add for Mr. Fiedler's information a few facts about the 2-cycle, having built both kinds for years.



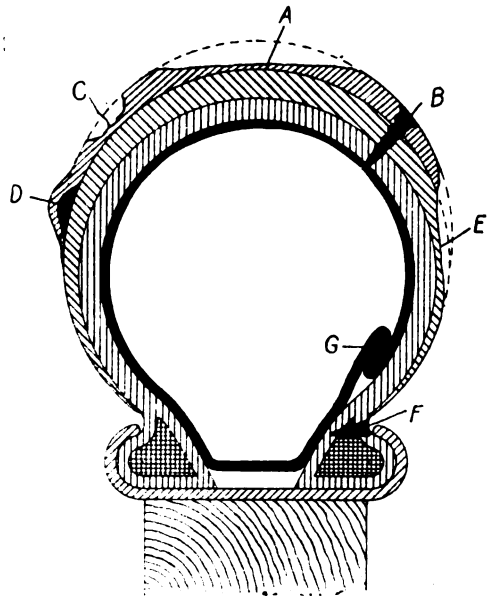
I think the reason why a 2-cycle idles badly is not that the diluted mixture will not fire properly, as you seem to believe, but that the quantity of mixture is not large enough as you correctly state. The assumption implied in your answer is that a 2-cycle must have larger charges than a 4-cycle if it is to fire equally as well when idling. I think this unfounded.

Engine experts know that a compressed charge fires better than one not compressed and so the 2-cycle should and probably does fire better at low throttle than the 4-cycle, because it always compresses since it fills its cylinder from the exhaust if it does not get a cylinderful from the supply, whereas the 4-cycle has very little compression at low throttle. That this compression causes a loss of power is mostly incorrect. The heat of compression is less than the heat of the fired charges and instead of losing heat it is likely that the compressed charge gains heat from the walls and actually gives more power as it expands than it takes to compress it. At any rate the loss is very small, if there is a loss, as can be determined by trial by spinning a hot engine. The faster it is spun the easier it spins. The idling speed is usually faster than one can spin by hand.

That cutting off the spark from half the cylinders makes it run as steadily as a 4-cycle is correct and for the same reason. It then fires the same number of charges as a 4-cycle and does nearly the same work. This would seem to prove that the dilution of the new charges with the old gas does not interfere with firing. Experiments with scavenging carried on largely 20 or more years ago and occasionally since, show that the presence of the hot burned gases is not particularly detrimental. These hot gases heat the new charge making it more perfect and easier to ignite. An equal amount of fresh air is more injurious in spite of the fact that every day or two some inventor bobs up with a new scavenging plan.

Otto on the one side and Crossley and Atkinson on the other, fought this matter out many years ago and Atkinson's theoretically perfect engine is made no more. I feel sure the important matter is the amount of fuel burned and amount of work done. The friction of the 4-cycle engine is much larger than in a 2-cycle because of the double number of pistons for a given number of fired charges and because of the friction of the cams, camshaft, valves, valve lifters and valve springs. All this work requires considerable power and the charges which give this power are certainly much larger and more sure to fire than the small charges needed to overcome the much less friction of the 2-cycle with half the number of pistons as compared with charges fired. But put a light brake on the 2-cycle to give it a load as the 4-cycle gets from its great internal friction, and the 2-cycle at once fires steadily.

All these things point to the friction loss of the 4-cycle as the cause of its steady idling. If people prefer this loss and good idling to a much higher economy and poor idling then makers must supply the friction. The most economical way to do this is to cut off the fuel supply of half the cylinders of the 2-cycle. But cutting off the spark serves very nicely, and this can be done by a large switch on the dash as per sketch. The gaps in this switch must be large. As large as ¾ of an inch is preferable. And the switch must be kept dry. Water on it will carry off the spark. If four levers and posts are provided any cylinder can be cut out. The levers are grounded on a common ground wire. The posts are connected by high tension wire to the plugs or plug wires; one post to a plug. Any maker of switches can supply posts and levers. The base may be of hard rubber, wood boiled in paraffin or thoroughly well varnished with shellac.



To cut off the spark.

Common Causes of Tire Troubles.

The natural wear of the tread surface of a tire is shown at A, in the illustration. But if a number of the layers of fabric comprising the body of the shoe are cut, this also constitutes a weak place in the casing and a blow-out will be the result, as shown at B, because the few layers of fabric remaining do not have sufficient strength to resist the air pressure. A stone bruise as shown at C, is caused by the removal of a portion of the rubber tread by a sharp stone, glass, etc., and is often more serious than a puncture, because it removes some of the tire surface. A sand blister as shown at D, is pro-

Digitized by Google

duced by sand or grit from the road working into a space in the tire, between the tread and the fabric body, through some neglected incision or bruise. The side of the tire is often chafed as shown at E, by running the tires against curbstones, or driving in car tracks. Rim cutting as shown at F is generally caused by insufficient inflation, which permits the rim to cut into the tire and therefore tends to sever

Points to be considered for wear.

the bead from the side of the shoe. The chief inner tube trouble is penetration of the wall by some sharp object, or folding over of a part of the tube as shown at G, when the tire was put on.

The Signal Question.

From Gridley Adams, in The New York Times.—What protection is insurance to me, an automobile owner, after some one has run into me, or I have run over somebody? I have the loudest possible warning signal on my car solely for my own protection. In rainy weather, with the curtains up, it is absolutely impossible to hear some of the electric buzzers which are on some cars masquerading as horns. And as for rubber bulb horns, they are an absolute farce, and even pedestrians in crossing streets now pay no attention to them, because of the laughing stock made of the "honk, honk," on every vaudeville stage.

Recently I was party to an automobile accident which cost me a considerable amount, and yet for which I was in no way responsible. When riding, other automobiles will pass you and come within a foot or less of your car, all without even sounding their warning. I might see a rut in the road and turn even the very slightest in order to prevent my wheel going into the rut. Not knowing that the other automobilist was to pass me, I would, of course, bring about an accident. He might claim that I should have put out my left hand, indicating that I was about to turn, when the real trouble was that he should have sounded his warning signal, and had a warning signal loud enough for me to hear. It is the same with half the car owners when they turn a corner or are about to pass motor cyclists or boys on bicycles. They slide up alongside without giving the boys any idea they are so near, when a good, strong blast on their warning signal, while they were yet 50 or 75 feet away, would certainly keep the boys posted as to impending danger. Half the people who are injured might have saved themselves if automobilists had only thought to have sounded a loud enough warning in time.

I am heartily in sympathy with the Society for the Prevention of Useless Noises, but I certainly protest against any laws that will hamper a man's protecting himself. What they should have is a signal that can be heard above all road noises, and then be compelled to use it.

FOR THE GARAGE MAN.

Little Things Which Make for Success and Satisfied Patrons.

BY J. N. BAGLEY.

Hardly a day passes but the machinist comes up against things in his line of work that require study to meet the peculiar conditions, and the better he is at solving such problems the more successful repairman he is, and the more money he gets for his work. Not only this, but to arrange his tools and machines so that they are convenient often means the difference betwen success and failure.

Not long since the writer had a job which required a great deal of lathe work and to stand at the lathe and watch it would have consumed practically the entire time of the operator. To save watching the carriage as it traveled to the work, I installed an electric bell on the lathe bed, as shown at H, Fig. 1. To the lathe bed a clamp was fastened and the ground wire fastened to it. This clamp, B, could be adjusted along the bed at will and the adjusting point, D, could be moved for a close adjustment. On the edge of the carriage was installed a block of wood fiber, C, which was a non-conductor, and to this was fastened one of the wires leading to the battery. As the carriage, F, moved auto-

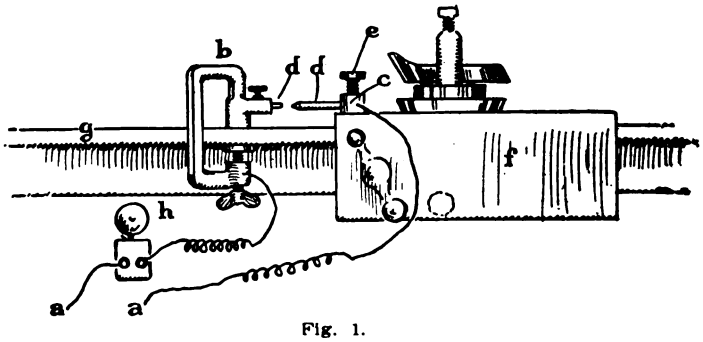


Fig. 1.

matically along the lathe bed, G, it would come up to the point on the ground, D, and connect the point, D, in the insulated block. This closed the circuit and the bell gave the alarm that the carriage had almost reached the end of the cut, and the operator then again started the cut. The wires, A, A, lead to the dry cells which can be placed in some out of the way place or in a box under the lathe.

After setting the lathe the operator could go about something else with no fear of forgetting his lathe, and thus accomplish a great deal of other work. Many times the operator might be absorbed in something else and the carriage could slip over and ruin a piece of work, but with the bell all the danger is eliminated as the minute it rings he will be attracted to his work. This switch should be set in such shape that it will alarm the operator in

Digitized by Google

plenty of time, so if he should be a little distance away, or in case he had his hands full he would have time to reach it and take care of it.

In Fig. 2 we have the same alarm applied to the feed of the press drill, which can be used in drilling a number of holes to gauge the depth. I have found

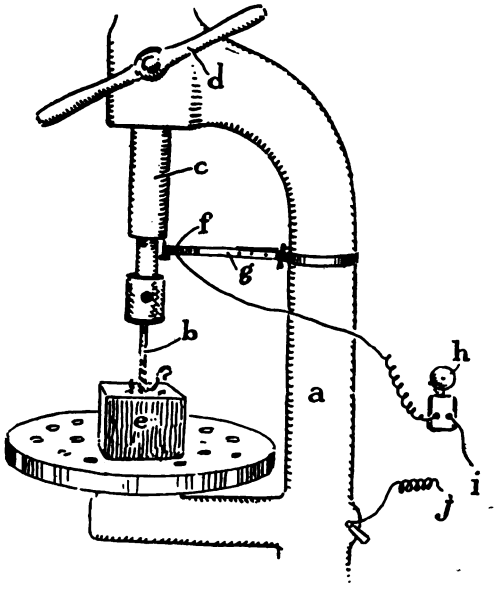

Fig. 2.

it works well and gets the holes near enough for ordinary work. The strap, G, bolted around the frame of the drill, carries on the end a block of fiber which is a non-conducting material and to this is fastened one of the wires. The other wire is grounded to the drill frame where handy and out of the way. The adjusting screw in the end of the fiber block can be screwed back and forth to make close adjustments. This should be arranged so that when the spindle comes down as far as required it will close the circuit by bearing on screw, F, thus ringing the bell. The drill, B, can then be raised from the work, E, and the second hole drilled in the

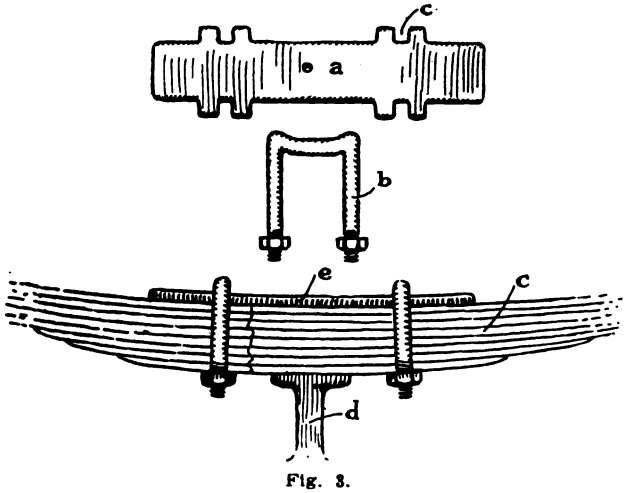

Fig. 3.

same manner. In case the feed is done with the hand lever, D, it can be moved just as little as necessary, and in case the feed is controlled with a ratchet device it will be necessary to release it the instant the bell rings or better still just a trifle before, and make the least fraction of an inch by hand. In case the spindle, C, does not have a shoulder to come against the screw in block, F, it will be necessary to make a small clamp for the ground contact. In case the frame, A, is covered with a heavy paint it may be necessary to scrape a bright spot to get a perfect ground contact. Connect the batteries to wires I and J.

We have in Fig. 3 a handy repair device for use on car springs which can be made at odd times and sold to the tourist quite readily, and many times they come handy for the garage man as well, for a new spring is not always at hand when wanted. It consists of a bar of iron made in the shape shown at A, with glides on the ends to prevent the clamp from slipping out of place. The clamp with bar for securing to the spring is shown at B. At C we have a broken spring with the repair bar, E, in position. D is a cross section of the front axle which in no way interferes with the use of the bar unless it be the small bolt which passes from the top up through the spring, in which case it will be necessary to drill a hole in the bar at A, to pass over the nut and leave an even bearing on the broken spring. There is hardly a tourist but what will be interested in repair bars and they should be made up in different widths so they will accommodate the different width of springs in use on different makes of cars.

In Fig. 4 we have a gear with a broken tooth. This is a common occurrence, especially with the cast wheels used in much machinery. In this instance it is but necessary, in case the rim is heavy

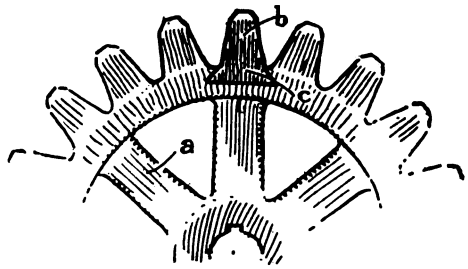

Fig. 4.

enough, to cut a dovetail in the rim and make a steel tooth that can be driven as at B. The notch, C, should be a trifle larger at one side than the other, to allow the tooth to wedge tight as it is driven in. A number of teeth may be put into the wheel, A, providing they are not two together, but in this case this can be done, except it will be necessary to braze them, while with the single it is but necessary to saw the two sides off, leaving them to project just enough to head a trifle, preventing them from creeping sidewise. In case the teeth are inserted in steel wheels they can be brazed; in fact it is advisable, as spelter flows well on steel while it does not on cast iron, unless conditions are very favorable. A tooth placed in a steel wheel in this manner and brazed will in nearly every case last almost as well as the original tooth.

Occasionally there comes a job to the shop which at first glance looks impossible to do without special tools. But it depends on the ability of the machinist to handle work of this kind, for any one can do the simple jobs.

On one occasion a large wheel was brought to the shop. It was to work in a certain place and the face of the wheel was a half inch too wide, and if this face could not be narrowed up it would be necessary to have a wheel made to order or rebuild a cement foundation. The largest lathe in the shop was a 24", and the wheel measured 5'-4" across. This looked like a difficult job and the man who brought

Digitized by Google

the wheel suggested we cut it with a cold chisel. We advised him that he could come back in the evening and we would have it ready. We turned the head stock on the large lathe, end for end, and bolted the wheel to the face plate and let it hang along the outside of the lathe, as shown at C. The face plate D, being quite small compared to the wheel, we used a number of bolts to make it secure. We ran a shaft through the head-stock B, and through the head-stock B, and through the center of the wheel, which aided quite a little in truing the work and saving some time. The dotted line G, shows the amount to come off the rim of the wheel, and to remove this we placed alongside the wheel a 13" lathe and fed the tool into the work with the cross-feed of the small lathe. The small lathe E, was so heavy that it did not require fastening to the floor. The tool F, was a little longer than the ordinary tools used for turning as it was necessary to reach it over the bed of lathe E, in order to come to the rim of the pulley. Three hours from the time the pulley was brought to us we had it turned and our machinery all placed back in position. We called the owner and told him he could get his wheel. He inferred from that that we could not do anything for him and in a few minutes came with a dray to

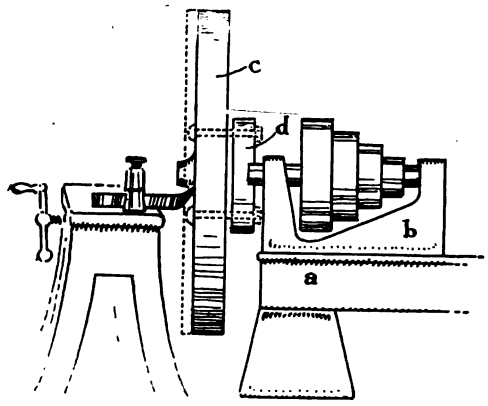

Fig. 5.

take it away. He was a surprised man when he saw the job and looked all about the shop to find the tools we did it with. When he paid his bill in addition to the price we charged him for the work he made us a present of a five dollar bill and while he was a contractor he sent us all his work from other towns near us. These jobs do a great deal in advertising one's business and should be attempted if possible.

Now in case we had been fortunate enough to have a lathe large enough to handle the wheel he would have thought nothing more of it than he would of having a bolt or pin turned, but it was putting into use ideas to meet conditions that attracted his attention, and it nearly always works out in that way. This idea can be worked on large irregular castings as well, or for boring the hubs of large wheels. Of course, if two lathes are not at hand it would be a little more difficult and the tool for boring or cutting would have to be handled in some other manner, but there is hardly a shop but what has some device which can be arranged to do the work, depending on the ability of the workman.

A handy device which comes in play about the garage and can be made at spare times is shown in Fig. 6. This consists of a double box as shown in the drawing at I. The compartment H, consists of a frame which is hinged at the bottom to the box I, and has a plate glass front which covers the instruments which are controlled by switches on the top of the box A, B, C, D, E. The switch E, operates or brings into the circuit the ammeter for testing the amperage of the batteries; D, brings into circuit the voltmeter which indicates the voltage; C connects into the circuit a small light which lights the board for use after night; B brings into the circuit

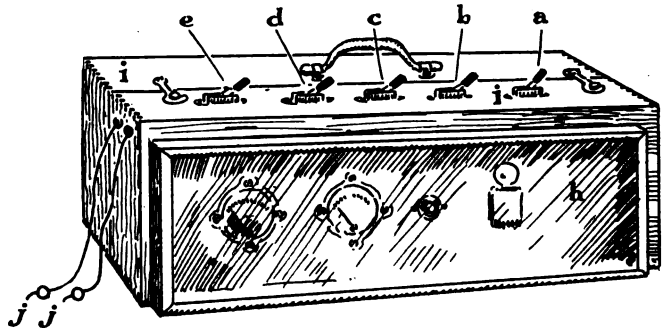

Fig. 6.

the bell which rings when testing wires for an open wire because of a broken wire or a blown fuse. The terminals J, J, lead off to be used about the car. In the back of the box is a set of batteries and by closing the switch A, connects them up in such manner that the batteries can be used independent of the instruments for cranking a dead car. Now by opening the switch A, and closing the switch B, we have the bell in the circuit for testing the wiring out on the car. By taking the one wire J, at one end of the car, say the headlight for instance, and going back to the starting point of the wire, it will immediately show that condition of the line. Now in case we find the line O. K., and yet the lamp will not burn, it will be necessary to test out the globe to see whether or not it is burned out. We now open all switches and close A. This passes the battery current through the wires, and by attaching the wires J, J, to the lamp wires leading to the globe, will tell whether or not the globe is in good condition. If it is all right it will burn, and if not it will remain unlighted. In case we wanted to test the voltage of the battery we would open the switch A, and close the switch D, which when the wires J, J, were connected to the positive and negative ter-

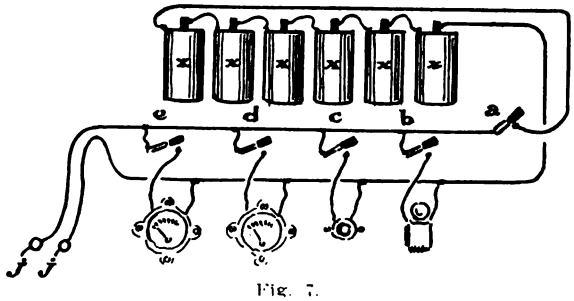

Fig. 7.

minals, would at once show the voltage on the instrument. Any time it is necessary to test out the wiring in the box the switch A can be closed, and any of the other switches closed and the instrument will record the condition of the batteries in the box. At K we have a handle located on the box so as to balance it for carrying it about when wanted from place to place.

In Fig. 7 we have a wiring diagram for the above described test box, X, being the batteries in the back of the box, and the wires J, J, leading from them, except that switch A breaks one of the lines.

Digitized by Google

The instruments each being connected with the line above, and one of the wires being broken by the switch, of course enable the operator to cut the instrument out and in at will. If the ammeter used on the board is the ordinary instrument used to test dry cells it should not be connected into the line with a storage battery or it will be burned out in an instant, as they are a higher amperage than the dry cell. In case the ammeter is to be used on storage batteries it should be ordered special. A voltmeter testing up to 30 volts will be sufficient for ordinary service and the lamp should be six or seven volt, 12 to 15 candlepower.

GRADE CROSSINGS.

Every Day Adds Another Case of Foolhardy Narrow Escapes.

J. A. McCrea, general manager of the Long Island Railroad, says it is a wonder to him "that at least a score or more of people have not been killed or seriously injured through the continued recklessness of automobile drivers. Every day we are getting reports to the effect that the crossing gates at this or that place have been broken by drivers who thought more of speed than of safety.

"If one operates a machine he should remember the slogan 'Safety first, safety last, and safety always.' He should never venture over a railroad grade crossing unless he stops and looks along the tracks in both directions. Private chauffeurs should be compelled to follow the same instructions.

"Travelers on highways," concluded Mr. McCrea, "should in case of doubt take a safe course, and thus secure a margin of safety. Rushing over a crossing 300 feet ahead of a train has no margin of safety." Mr. McCrea cited as typical cases the following "near accidents," which have occurred during the days mentioned:

June 24, at 5:15 P. M.—Despite the upraised hands of a patrolman warning traffic on the highways to stop because a train was approaching, the driver of an automobile recklessly drove his machine over the crossing, near Jamaica race track, while the gates were being lowered. Fortunately, the only damage was a broken gate.

June 25, at 5:30 P. M.—Mrs. Curley, of Rockaway Beach, drove her automobile, containing another passenger, over the crossing at Arverne before the gates on both sides of the tracks were raised by the gateman after a trolley car had passed the crossing. The automobile broke off about six feet of the furthermost gate. The front wheel of the automobile came off, and the windshield and one of the lamps of the machine was broken. Neither Mrs. Curley nor her companion were injured.

June 26, at 6 P. M.—Although the gates at the Park Avenue crossing in Far Rockaway were lowered for an eastbound trolley car, a driver jumped off the wagon he was driving, raised the north gate partly, and beckoned to the horse to proceed. The horse cleared the gate, but the top of the wagon came in contact with the gate, breaking off about 15 feet of same. He then led the horse over the tracks, and the approaching trolley was compelled to stop short to avert a collision. After escaping danger so narrowly the driver raised the south gate, passed the horse and wagon underneath it, and quickly disappeared.

June 27—While the gates were lowered at Ozone Park, at 1:25 A. M., because of approaching electric trains from east and west, the driver of automobile ran the machine recklessly into the northwest crossing gate box. The only damage done was to the automobile's radiator, In the machine with the driver were two other occupants.

June 27—Two automobiles almost collided with an eastbound train at the first crossing east of Cutchogue. The engineer sounded his whistle at the prescribed distance from the crossing, but the auto drivers refused to heed the warning of danger ahead. One of them deliberately speeded over the crossing, beating the train by a few seconds. The other motorist drove his machine right up to the edge of the tracks, and, seeing the train practically on top of him, quickly backed onto the highway just in time to miss being either killed or seriously injured.

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1638 Starting, Clutch and Lighting.

From H. D. Pierce, New York.—1—I have a Flanders 20 automobile with a Splitdorf low tension magneto. At times it is impossible to get a spark at the plugs with a set of dry batteries. I can start the motor on the magneto with one turn of the starting crank, except in very cold weather, and do not have to advance the spark from regular running position. I have examined the coil and magneto, put in new wires and cleaned and adjusted everything on the magneto, but still have the same trouble. It has acted the same for a year. I am sure the trouble is in the magneto, because when it has been running on the batteries I have cleaned the magneto and then been unable to start on the batteries again. Last Thanksgiving Day I had to shift switch about every three to five minutes from one terminal to the other. The motor would not spark more than five minutes on either batteries or magneto at one time, but would continue to run if I threw the switch before it came to a dead stop. I looked over the magneto, wiped off the oil, tightened the wires and put on some wires. Then it ran for some time apparently all right. Can you tell me where the trouble is? 2—The cone clutch grips too quickly on this car, unless I use lubricating oil and graphite, mixed with graphite on it once a week. Do you think the leather is worn off the face of the clutch? 3—How many cells of dry batteries of 20 to 30 amperes would it take to furnish current for a 15 candlepower 6 volt light? I have not noticed any

Digitized by Google

one having the same trouble with a magneto that I have.

Reply.—1—The coil, distributor, secondary wiring, circuit breaker and condenser are working properly, else the engine would not run properly on the magneto, as all these parts are in the same circuit when current is furnished by either battery or magneto. Your trouble must be in the primary battery wiring, or in the switch. It may be that "grounding" the magneto circuit also "grounds" the battery circuit. In the magneto or off position the battery circuit should be open, and in battery or off position of the switch the magneto circuit should be "grounded." You should look to the adjustment of the contact points in the breaker box. Be sure they come together squarely and that all oil is carefully wiped out, and that the insulation to the binding posts is clean. 2—You have ruined the leather facing to your clutch, burning it up with mineral oil. A little neatsfoot oil, or ordinary lard, would have prevented its grabbing. If it would not hold, a drop or two of castor oil should have been used. 3—Four, eight, twelve, sixteen or any multiple of four dry cells. If you are to use but four connect them in series, the carbon of one to the zinc of the next, etc. If a multiple of four connect each four in series and then connect the carbons of each series together and then by another wire the zinc. This will give you multiple-series connection, the voltage being in all cases the same and the voltage increasing proportionately with the increase in the number of series connected cells. Each cell will furnish approximately 1½ volts. You will find that a 15 volt lamp will take a lot of battery energy. With a proper reflector a 6-volt mazda lamp will give good illumination.

1639 **His Engine Trouble.**

From Clarence F. Nelson, Rhode Island.—I would like you to help me out of some engine trouble that I have with my six cylinder Rochester engine. It has been giving me trouble ever since I bought it. I have just overhauled the engine, put in new rings, new cam rollers, and stopped all air holes in the suction pipe and valve cages. I have also had the magneto repaired by the Splitdorf people, which is of low tension type with coil. The valves are set right by the marks on the gears, which is exhaust, closes 9 degrees after center and the intake opens 12 degrees after center. If I set the magneto to spark at or a little after the center the engine will start all right, but will not fire on all cylinders evenly and has no power, but if I set the magneto to spark retarded about three inches, measured on the fly wheel, before the dead center this will give about four or five inches before the center. When advanced the engine will run good and have plenty of power, but of course it is hard to start and gives a bad kick if I don't pull the crank up quickly. Please let me know what you think the trouble is. I have spent a lot of time on this engine trying to find the trouble, but the only place it seems to be is with the spark timing. It works the same if running either on the magneto or the battery. I have also tried a new coil. The firing order is 1-4-2-6-3-5. This is different from other six cylinder engines I have seen.

Reply.—It is well for you that your engine misses explosions with the spark set on center, for there are no conditions of running that should have such setting, else you would soon boil the water in your radiator and waste gasoline. When you set the spark ahead of the dead center you advance, not retard it. Our advice is for you to start the motor with late spark, and as soon as started, advance it, and when running keep it advanced as much as possible without causing the engine to "pound."

1640 **The Ford Car and Gasoline Saving.**

From John B. Scott, Nebraska.—I have a model 1912 Ford roadster that I have run over 15,000 miles and for actual breakage it has cost me $6.50, and that was caused by the carelessness of a garage man. This car to all appearances is as good as when unloaded and in fact it runs much better. I am able to make on an average over country roads 30 miles to a gallon of gasoline. I have made some changes in the equipment. The old coil system was very unsatisfactory—too much jumping, jerking and knocking. I had installed a Splitdorf Ford special high tension magneto and ever since I have forgotten what a skip, jerk or knock is, and she will pull to the last breath and never a knock or jerk on the hill no matter how steep or long. I have also installed a Danver oil system which I find to be a saver of oil and makes a much better running engine. Also a gasoline saver which is controlled from the steering post and this device I find is of considerable benefit, but it is a little difficult to properly adjust according to the amount of gasoline being used. I am using my second set of casings which are good for several hundreds of miles yet. Before starting out I go over the car and see that everything is all O. K. and keep the carbon out of the cylinders.

I noticed a contrivance being advertised for the Ford called the Automatic Gasoline Saver. This device fits between the carburetor and manifold, and the opening and closing of throttle opens and closes the device automatically, claiming this to be the most successful way of admitting air above the carburetor as it always come in the right proportion. This device is sold under a guarantee or money refunded. Do you think this kind of a device would be a success?

Reply.—We see no reason why the device referred to might not be useful. At all events, there would be little risk in trying it, since it is guaranteed or money refunded, something desirable in the case of anything new which has not been fully established.

1641 **Who Was to Blame?**

From F. W. L., Pennsylvania.—I wish you would give your opinion concerning the responsibility for the following accident: Both cars were going the same direction, No. 2 car was ahead of car No. 1, when car No. 2 pulled to the right side of the road. The driver of car No. 1 thought that the driver of car No. 2 wanted him to pass, for the reason he pulled to the side of the road. Car No. 1 then proceeded to pass. At this point the driver of car No. 2 did not give any signal nor look before he turned to cross to the left, in order to get in the private lane to his residence. Car No. 1 then, seeing him turn, also turned further to the left, putting on the brakes, and ran to a 3 foot bank and upset, throwing all the occupants out and striking No. 2 car just a little, the driver of which never stopped but proceeded right into his lane. The driver of No. 2 car

Digitized by Google

saw the other car about the time he turned, but did not try to stop or turn off to avoid the accident. Now car No. 1 did not signal before he attempted to pass for the reason that the car in front pulled to the side of the road which was taken as if he wanted the car behind to pass. The occupant of car No. 1, that was upset, had his arm broken, and wants to sue the driver of the other, car No. 2, for the doctor's bill only. He claims that he should have signalled or looked before crossing the road to the left. What is your opinion about it? I wish also to say that the driver of the car that upset has driven cars for eight years. The other driver only about one month. Of course, if the driver of car No. 1 had not ran to the bank he would have smashed right into the other car. Car No. 2 was not going very fast as it crossed the road and the driver could have easily stopped after he saw the car. Car No. 1 was going faster in order to pass, and would have succeeded in stopping also, but the road was a little muddy and the car skidded some distance. No. 1 car tried to avoid the accident, but No. 2 did not.

Reply.—Assuming that your statement is accurate, as you no doubt intended, No. 2 car was to blame for the accident. Although car No. 1 should have given a signal when it attempted to pass car No. 2, car No. 2 was clearly in error in not giving a signal when it crossed the road from the right side to the left to enter the private lane referred to. A car has no right to stop or make a turn in any direction without giving a signal. If this be the case the car is always responsible for any accident that may be caused by the absence of such signal.

1642 **A Question of Contract.**

From Reader, New York.—A dealer in a given town takes the agency for a car and signs a contract in the early part of the year to take, say two in February, two in March, and four in April, paying therefor a specified deposit for each of the cars in advance. The cars are taken for the first two months and the dealer does not send in his order for the third month, four cars, on the time specified. On June 30th the concern from whom the cars were ordered, said concern having State agency rights, lose these rights and therefore the local dealer cannot order any more cars, and asks for the return of the deposit covering the third month. The concern which had the State agency right, refused to return the deposit, stating that the dealer did not live up to his agreement in promptly taking the cars, while they had the agency. Will you please advise us as to what is the custom in the trade? We understood it is the practice with most automobile manufacturers to return such unused deposits if the dealer does not order the full quantity.

Reply.—The rights of the parties involved are to be determined by the terms of the contract between the dealer and the agency. If the contract specifies that time is the essence of the contract and that the failure to order the specified number of cars at the specified times shall be treated as a breach of the contract, and that the deposit shall be liquidated damages, the question as to whether or not the dealer can recover his deposit is an open one. The courts have been very reluctant to enforce covenants for liquidated damages and generally require proof as to the actual damages sustained. If the courts in the State where the contract was drawn frown upon liquidated damages in a case of this character, the agency will only be able to recover the amount of actual damage sustained by the dealer's failure to take the four cars in April. As the dealer has already demanded his money back and has been refused, it will now be necessary for him to consult a lawyer who can bring suit to recover the deposit, when the question, if any, as to liquidated damages, can be thrashed out in court. The practice and custom of other automobile manufacturers to return such deposits has nothing to do with this case, as quite likely the question of rights and remedies are specified in the contract. It may be remarked that where manufacturers return the deposits of dealers, they probably do so from other than enforced or compulsory motives.

1643 **Hard to Crank.**

From E. M. Couch, Nebraska.—I have a Buick, model 27, 1911, 30 horsepower, which has run about 16,000 miles. My trouble for the last year is in being hard to crank up. After it gets started it runs fairly well. I have ground the valves, and also looked for leaks in the intake manifold, but still it is hard to start. If you could tell me where my trouble is, in your next issue, and the remedy, I will be much obliged.

Reply.—There are so many reasons why an engine will start readily and so many little conditions which may be present, that it will be impossible within the limit of this reply to mention more than generalities. Broadly, failure to start readily may be caused firstly by defective ignition, secondly by imperfect carburetion and thirdly by structural defects or faults. You neglected to tell us whether the battery or magneto had shown anything from which to diagnose the possible if not probable cause of your trouble, nor of attempts you have made looking to better your carburetion, or whether during the past four or five years of running it has had a systematic and thorough overhauling by some qualified automobile mechanic. If equipped with the original carburetor this might be one cause, as it takes a better and more modern designed carburetor to vaporize gasoline to-day than in 1911. Your inlet valve stem bushings may have become worn. To our mind your only remedy is to have the motor thoroughly gone over, worn parts renewed and adjustments properly made.

1644 **A Leaking Carburetor.**

From Joseph Pernot, Wisconsin.—I have a Ford model touring car with a Kingston carburetor, which has been leaking gasoline, and would like to have your advice. I first thought it was due to the cork float and I took it apart—that is the carburetor—and examined it. I also had the cork float out and gave it a coat of varnish. I let it dry and then put it together again. I then started the motor with everything working lovely, but afterward it still leaked, and I thought it leaked around the hub which holds the connection of the two different parts. So then I took it apart again and put in a leather washer inside of the bowl, where the two parts come together, and put white lead on the screw threads and also on the bottom of the outside of the bowl, just before putting on the hub. After I got it all to-

Digitized by Google

gether again I started the motor and everything went fine, but it still leaked. I took it apart the third time and I had it all apart this time, that is I had all the balls off and cleaned them and put it together again, and it still leaked. I then examined it again and found out it was not due to the cork float nor the hub that holds the connection, but it is inside of the connection. There is a hole the size of a match which goes through the upper connection of the carburetor; that is, this hole is connected to the air current chamber. I am quite sure that the gasoline leaks through this hole, but do not understand how to stop it. I turn or shut the stop cock on the bulb when the car is idle. The carburetor does not leak when the motor is running. As the leak is not very fast you have to watch it for about a minute to see a drop. The motor runs fine and the leaking does not affect it at all. I sometimes think of getting a new carburetor, but the new one may leak as well as this one. I will wait and see what information you will give me.

Reply.—We can't quite understand why your carburetor should leak, owing to the source you refer to. If we were in your place, and your motor runs all right, we should not worry very much about a little leak. It is far better to have the car run correctly than stopping a drop of gasoline a minute, and not have it run correctly. We know very little about the Kingston carburetor, but it seems to us your better plan would be to shut off the gasoline when you stop and open the train trough, letting out what remains. Then you surely would not be bothered with leaking when the car is idle and when you are on the road and want to stop for a few hours, the occasional drop would not amount to much. On the other hand, if you think it advisable you might write to the Byrne Kingston Company, Kokomo, Ind., and explain your trouble to them. The firm has no office in this city.

1645 **His Motor Misses.**

From Dr. H. E. Wilkinson, Maine.—I am writing to find out if you can help me to diagnose my trouble. I have a Cartercar touring car, model 5A, 1912, which is equipped with a Schebler model O carburetor and Briggs electrical system. There isn't any name on the magneto, so I judge it also is a Briggs product. I am having trouble with the motor skipping, especially when it is working hard, as on grades and hills. When trouble first became manifest I had run about 7 miles from home, over a quite hilly road. When it began skipping I regulated the carburetor thinking it was there, and came home without any trouble whatever, but every time since then I have been unable to go any distance without its skipping, and on a hill of any size I have to disengage the clutch to let the engine pick up. After it starts skipping it seems as though it is only one cylinder and sometimes two would fire. By disengaging the clutch and retarding the gasoline throttle the engine picks up, but if there is any grade it will miss again. This happens on all speeds on hills and grades. This trouble is continually growing worse, so that it will sometimes skip right on the level, but by switching on to the batteries for a moment, then back on to the magneto, it will pick up all right for a while, but on hills this doesn't help any. I thought the trouble was in my carburetor, but am unable to get any adjustment that works. I have tried adjusting while running, etc. The engine will not pick up without skipping, by opening the throttle quickly, especially on the magneto. I will get an adjustment that seems to be all right but in a few minutes it will act the same as before. It will pick up better on the batteries than on the magneto. I have taken the carburetor apart and find the float O. K. The needle valve works well. When the motor is shut off it will run quite a while and the carburetor will seem to run over, but it has always done this, so don't think it has anything to do with the trouble. I get a good spark from them when out of the engine; also by grounding the plug wire on the engine. I have cleaned all points in the breaker box and the magneto; also polished connections on wires that go into the magneto. If you are able to give me any insight into the trouble it would be greatly appreciated, as I am a long way from an expert garageman.

Reply.—Your trouble is in all probability due to the carburetor. This model is no longer manufactured by Wheeler & Schebler, Indianapolis, Ind., for the reason that it did not fulfill their expectations. You will find that the model L Schebler is better than the model O, while the very latest model R is still better. At low engine speed the spark furnished by the battery is hotter than that furnished by the Briggs magneto.

1646 **Hard to Start.**

From Harry E. Smith, North Dakota.—I am having trouble with my model T, 1913, Ford runabout. It has run about 5,000 miles and is equipped with a Holley carburetor. My car is hard to start in the morning or when it stands all night. It never did that before. One morning I cranked it and primed and it would not start. Then I found that one spark plug was out of order, the spark coming out of the side of it. I replaced it with a new one and next morning it started all right. The morning after that I had an awful time to get it started again, but after I get it warmed up and started once, I can start it any time of the day the same as I always did. It just seems to be that way when it stands over night. I have put a new timer on and a K. W. master vibrator.

Reply.—A later model of carburetor, one that will vaporize the present heavy gasoline should help you. The older model of Holly carburetor, such as were sent out with 1913 cars will be found not so satisfactory as the 1915 model, especially when starting a cold engine.

1647 **Spark Trouble.**

From G. E. Kinzie, Iowa.—I have a few questions I would like to ask you. On two different Ford cars I have had trouble getting a spark to the plugs after the master vibrator was installed. On the first car it was a K. W. master vibrator and I believe a Kingston coil. They had been put on by another party and I was called several mornings to help start the machine. This equipment had been on for several months but was going to give trouble now. I got an extra good buzz at the master vibrator but no spark at the spark plugs, except occasionally just a thread of a spark and most of the time not even that. This man had these visible sparkers on the top of his plugs and I tried changing the distance of the gap of these visible sparkers and looked the

Digitized by Google

wiring over very carefully. The coil was properly shortened on top and the vibrator screwed down, and the batteries, 4 of them, tested about 25 to 28 amperes each. Does a master vibrator have a condenser? I concluded that the condenser in the master vibrator was damaged and put on a new J & B master vibrator, but that did not help matters, so I disconnected the vibrator altogether, and though the platinum points on the coil were in very bad shape, the machine started right off with a "fat" spark. The platinum points on both master vibrators were in good shape, especially on the new one. Just a few days ago I spent some time in hunting ignition trouble on a Ford car, which by the way has existed for four years, ever since the car has been out, though the car to-day is just as good as new, the lady owning it having cared for it like a piano. This car was equipped with a Kingston master vibrator coil, and hard starting was the order of the day. I tried putting platinum points on the Kingston vibrator instead of the material they use for that, but it did not help any. The trouble seemed to be that the magneto did not give forth any spark, when cold, just after standing over night in the summer time. There were visible sparks also on all these spark plugs and when the engine was cold, no spark would appear at the plugs from the magneto, but when warm or hot a spark would jump the gap, though you turned ever so slow. The magneto tests about the same as all Ford magnetos that give good satisfaction. I decided that it was a coil trouble and put on a Splitdorf coil. I knew that was a good one, and I also installed four new dry batteries testing 28 amperes each. The machine worked better, but I thought a master vibrator would improve it still more, so I installed a new J & B master vibrator. Immediately the spark from the batteries only made a mere thread across the visible sparkers on top of the plugs, though an extra good buzz was obtained. On this machine the magneto works all right, but on the other one neither one would spark. Now I have removed the visible sparkers which helps the trouble and it runs real good on the magneto and a little on the batteries. I added two more batteries which made a better spark, but I thought that was too many so I took off one, leaving me five new batteries. I believe that four batteries would only make a mere hair of a spark, and most of the time no spark at all jumps the gap. Now I am used to hunting for troubles of all kinds, but this has got the best of me. Strong buzz, good connection, wiring all new and carefully put on and wired up like I wire all of them up, and yet only a mere thread of a spark and most of the time not even that. No. 1.—What are the volts in dry batteries used for? 2.—What are the amperes used for? 3.—If in connecting the batteries from the carburetor to zinc, and in that way raise the voltage, how does it come that a machine does not use the volts, and if it does, then how does it happen that all our old batteries, without any amperes at all, have just the same voltage as they did when new. In other words, what is the use of increasing the voltage if the engine uses amperes. 4.—How do you connect to raise the amperes; and how the voltage?

Reply.—In general we have to say that your apparent lack of knowledge of the principles of elementary electricity leads us to believe that the ignition of the motors in both cases could have been perfected very easily had you been supplied with and followed correct wiring diagrams, or had studied and mastered the instructions usually supplied master vibrator purchasers. It looks to us as if the wiring were improperly done or that primary wire were used for the secondary leads from the coil units to the spark plugs, although using regular spark plugs, such as are sent out with Ford cars, might have given the desired intensity to the spark appearing at the plug terminals. Outside spark gap plugs, visible spark as they are sometimes called, are much more liable to break down or leak current through the insulators than are regular well made plugs. We believe your first attempt to locate the trouble should have been to use a new plug in each cylinder, after which a set of spark coils from a car which runs properly should have replaced the set of coils being used, for proving whether or not the trouble were due to broken down primary or secondary coil windings. With a good buzz at the master vibrator, which by the way, is supplied with a condenser, it only shows that there is plenty of current. You can make the master vibrator buzz without having the coil in the circuit at all. The mission of the primary wiring in the coil is to set up a surge of high tension current in the secondary wiring as the circuit is broken, and every time the small electro-magnets in the master vibrator attract the armature attached to the vibrator blade it breaks the current at the contact points, which permits the spring in the vibrator blade to carry the released armature end back to its normal position when the circuit switch is open. Master vibrators should be located in the circuit as close to the timer as possible, in order to overcome the inductance of the wire. If the current flowed from the battery to the switch and then to the coil windings, to the timer, and to the engine, to the battery ground, to the master vibrator and to the battery terminal this wiring might not give so good results as if the master vibrator were wired close to the coil terminals which are connected together. Your trouble may have been either in the coil winding, wiring or plugs. As master vibrators are frequently used in hopeless endeavors to correct broken down coils, your experience is not unusual. Motor car owners frequently try to see how long a spark they can "pull." While this is a sort of expensive amusement for inquisitive car owners it is a source of profit to manufacturers and dealers in spark coils, as probably more coils are ruined by this fool practice than from use as intended. Answering your queries in their order. 1.—The voltage of a dry cell is the measure of the strength of the current. 2.—The amperage is the measure of the life of the cell. 3.—From "carburetor to zinc" should probably read "carbon to zinc." Such connection is called in series. The voltage of a single cell is about 1½, and if four cells are connected in series the voltage of the current will be $4 \times 1\frac{1}{2} = 6$, the amperage being only that of the weakest cell. If all the carbons are connected together, and all the zincs, the connection would be in parallel, the voltage being still 1½ and the amperage the total of that of each individual cell. For demonstration purposes the flow of electric current is frequently likened to that of water. If one gallon of water is contained in a one gallon jar, four one quart jars would together hold the same quantity, and if all four are discharging at the same rate they would be emptied sooner than the one-gallon jar delivering at the same rate. No matter how large a cell of battery is made, or how small, the voltage remains the same, but the larger cell would last longer than a smaller one.

Digitized by Google

Four cells of dry battery, each showing 30 amperes, if connected in parallel would last, theoretically, four times as long as a single cell, while four cells connected in series would last as long as a single cell but would deliver a current of four times the strength or intensity. The quantity of electric current is expressed in watts, thus four dry cells of 30 amperes each would have a capacity of 180 watts or watt hours. You should be able to make them last four times as long by increasing their amperage through parallel connection as they would last if connected in series, for the sole reason that the voltage or strength of the current in the latter case would be four times as high, or of four times the strength or intensity. You cannot use parallel connection of dry cells for gas engine ignition, for the current will not be sufficiently strong. At least two cells are connected in series as for motorcycle ignition, or four in series for usual motor car ignition.
4.—Already answered.

SPEED MANIA FOOLS.

New Ones Are Born to Take the Place of All Who Die.

From Dr. Will B. Crawford, North Carolina.—Your timely and merited article in your most excellent journal touches a responsive chord in my heart. I have written several articles in regard to such matters, not only the dangers of "Grade Crossing Dangers," but also on speed mania fools and reckless and incompetent negro drivers. Only a few months since, during the session of our State legislature, one of our Eastern representatives took his negro driver with him to our capitol city, and this negro coming from the Country Club and seeing how fast he could drive over the macadamized roads, such as he was not accustomed to, and probably had never driven on before, in rounding a curve near the railroad crossing took the outside, as he was running too fast to keep to the inside, lost control of the big car and it went down the embankment, killing the Speaker of the House, also a very worthy young man, one of the clerks, and maiming the representative from our county, all of whom were in the car.

Now this was simply gross carelessness and all the result of speed mania in a country negro who, in all probability, had never driven on macadamized roads before, and who had not the slightest conception of the markings of speedometer, and cared less.

My observation has been that the average negro driver, in our section, and the majority of the white ones, have their knowledge of motoring limited to only three things, namely—how to start, how to stop and how to accelerate, and labor under the false impression that the faster they drive the better driver they are.

One would not think of getting on the train and feeling at ease if he knew the engineer had not been onto his job long enough to know his engine well, but our people will invest good money in a car and employ a fool negro or incompetent white man to run it when in all probability he knows no more about it than he would know how to drive an airship across the English Channel.

I get so impatient sometimes when I read the daily occurrences of lives being snuffed out by such inexcusable carelessness and fool speed mania that I am, as you say, almost ready to remark that it is what they deserve, but I throw the mantle of charity over it all and try to excuse them, thinking maybe some day the people will be aroused to a sense of their danger and require from every chauffeur the same qualifications which the railroad officials do of their engineers. Not until then will precious lives stop being sacrificed, nor the people along the highways be safe from the reckless, dare-devil driving which is an almost daily occurrence.

Nearly every day cars pass my home, on Central Highway, running faster than the train on the Southern Railroad, and the majority of the drivers who exceed the speed limit are negroes. One passed a few days since driven by a negro filled with white people which was running so fast that two dogs, trying to overtake it were outrun half the distance in a quarter of a mile. My wife remarked: "Suppose that fool negro was to lose control of that car, what would become of them?" I replied that it would not be much matter for them, placing their lives in his careless hands as they did, but that if the car overturned, or went into a ditch, at the rate he was going I did not think there would be enough left of all of them for a first class and decent funeral, unless they gathered up the fragments along the road in a basket.

There ought to be some measures taken to put an eternal stop to recklessness as is daily practiced not only in our small towns and cities but especially in the rural districts where we have no police protection. The very first move necessary would be to require all chauffeurs to stand examination and secure license, and then enforce the law to the letter in regard to speeding. To give you a fair sample of the negro drivers there is one who is doing service here who came to me to be employed to drive my car in less than thirty days after he left the cotton field around his father's cabin.

I asked him a few questions in regard to handling a car and he knew as much about it as he did the rule of three. He had no conception whatever of anything pertaining to the car but how to start, how to stop and how to turn on the gas. He knew how to pump wind in the tires but was ignorant of how to inflate them and thought he could keep it greased as good as could a "waggin."

I told him when he knew more about one than I did I would hire him. I have not yet heard from him.

A New Carburetor Idea.

From Dan A. McConnell, Idaho.—If a motor proves faulty, to find out if the trouble is really in the carburetor, take the carburetor off entirely, fill a teacup with gasoline, prime the engine and start. Hold the cup of gasoline under the intake where the carburetor was. The nearer the cup is to the intake the faster the motor will run if other things are all right.

For Foul Spark Plugs.

From W. T. Thielman, Jr., Michigan.—If you will permit me I want to offer a suggestion for Ford owners that have spark plug troubles. I was bothered with this trouble for a long time, and finally cleaned the screen in the brass cap that covers the breather pipe, which had become clogged with dirt,

Digitized by Google

thereby allowing the gases to escape, which are formed by the oil becoming hot in the base. These gases form a pressure and I believe this pressure helps force the oil past the pistons and onto the plug. In fact I have not been troubled with this trouble since.

Rusty Rims.

From Dr. L. W. Hendershott, Illinois.—I would like to say relative to the rusty rims "dope" in the June number, page 52, J. A. Hogg, it is far too thin and the quantity much more than most anybody would use. The way I put it up is this: Gasoline, 4 ounces; beeswax, 6 drams and powdered graphite, 6 drams, more or less, as you want the "dope" thicker or thinner. Shave the beeswax fine and mix in a large mouth screw cap can or container. Mix until all is dissolved, then apply to the leaves of springs, threads of bolts, wheel rims, etc. A party asked you some time ago what to apply to an exhaust pipe to prevent rust and you replied stove polish. Permit me to suggest, after removing rust that aluminum paint be applied, or if black is desired, use engine enamel.

A BLACKMAILING GANG

Which Exacts Tribute or Punctures Automobile Tires and Smashes Gears.

Although it is not of special interest to most of our readers, for the blackmailing of automobile manufacturers has not yet extended beyond the confines of New York City, yet some recent reported developments there reveal the fact that the automobile is a fruitful subject for blackmail, given sufficient moral turpitude and desperation on the part of the criminals and an easy-going acquiescence by the victims.

It appears by a report in the New York Herald, that the Saxon Motor Company has for some time been the vicitm of a gang of blackmailers, and that the local superintendent was badly beaten when payments were finally refused. The blackmailing has been done by what is called the "Gopher gang," a notorious band of loafers, some $10 or $15 a month having been collected for the past two years, not only from the Saxon Company but from a dozen other firms.

Finally it was decided that the crime had continued long enough, and the other day, when the superintendent was about to drive home in his own car, he saw a man jump in one of the company's vehicles which was standing at the curb, shove in a switch plug and start to drive away. The automobile was under headway when the superintendent jumped on the running board and pulled out the switch plug, cutting off his power.

The man in the automobile leaned over and hit the superintendent on the head, knocking him off the running board and causing him to strike his head on the pavement. His assailant then leaped from the car, ran around the corner and disappeared.

Employees of the Saxon service station, who had seen him fall, ran to the street. They put the stunned man in his automobile and drove him home. There a physician after examination said that a blood clot probably had formed and was pressing upon the brain.

Officers of the Saxon Company brought the attack to the attention of the police. As a result that neighborhood, which usually is without special police protection, has been guarded by detectives. It was said at the office of the Saxon Company that payment of blackmail was at an end and that probably another effort would be made to combine business firms in that neighborhood into a league for mutual protection.

Investigation confirmed the statement that the collection of blackmail by the Gophers was on a large scale. Merchants and business men were disinclined to have their names used, but many admitted that they paid the Gophers for immunity in one way or another.

Estimates of the amount collected by the Gophers varied from $5,000 to $10,000 a month. One large firm was said to pay $150 a month in the guise of voluntary contributions to balls and outings. Other firms were reported to pay $50. The rate for a business firm doing other than a purely local business was said to be never less than $10 and more often twice that amount.

Instead of tickets for a dance the shopkeeper may be asked to buy a ticket for a raffle on a gold watch on which no address or date is printed. This is said to be a favorite method of holding up chauffeurs whose business brings them into the Gopher territory. If a chauffeur does not buy he is apt to find his gasoline tank or a tire punctured by an ice pick. Sometimes his automobile is driven a short distance away, to be recovered later with tires slashed and lamps and gears broken.

But the gang promised more. They not only agreed to prevent their members from destroying the property of their "patrons," but according to the statement of one of their victims to a reporter of this magazine, if an automobile demonstrator chanced to get into trouble from fast driving or other infraction of local vehicle rules, they promised to see that he was not arrested, or if arrested to "get him off" in the local court. On the other hand if a policeman "got too fresh" they would "do him up"—all by the same token, so to speak.

A reporter of this magazine interviewed some one who lives in the vicinity of this band of grafters and was told that the "Gopher band" is a powerful organization; it numbers some prominent men and quite a number of much "political influence."

It would appear from the foregoing that the tribute givers themselves are not wholly immune from censure. Why this willingness to pay to secure immunity for the misdeeds of its employees or to have the officers of the law attacked? Yet quite likely if the blackmailed firms were assessed a little more taxation for the purpose of securing more policemen and proper protection against lawlessness they would have made a howl.

The motorists should give special care to seeing that the mud guard beneath the engine and gearing is kept free of volatile oil for the reason that at any time a little gasoline might get in with it and start a fire.

The split sheepskins that are sold for chamois skin make very good dry wipers for car cleaning, but if the least amount of grit or sand gets on them they will scratch the surface badly.

THE CHEAP AND THE EXPENSIVE.

Buying a cheap car may be a good deal like buying a cheap coat or pair of shoes, or a cheap tool or article of furniture. The cheap article may be the dear article in the end. And not only that but it may give far less satisfaction while being used as well as a far shorter term of use.

That well known proverb, "The destruction of the poor is their poverty," is literally true in relation to their tendency from lack of means to purchase things of an inferior quality. For there is a point in material and construction which transforms intended economy into extravagance and waste.

It is safe to assume that not one person in ten ever regrets purchasing a high grade car at its commensurate cost, and possibly it may be as fair to assume that nine out of ten regret they purchased a low grade car at a fair cost. It should be understood we are referring to the extreme of low-priced cars and the extreme of high-priced cars—or rather to the extreme of inferiority and the extreme of good quality, without special reference to price.

Bear in mind that it costs just as much to machine any part of an automobile made of poor material as to machine it if made of good material. It costs just as much to assemble the parts of a car when made of poor material as when made of good material. And the making of these parts and their assembling constitute the bulk of the cost of the finished car.

We do not say that very good automobiles indeed may not be had at what may be considered low prices, but in the case of well-established manufacturers, price and value correspond more nearly than is generally supposed.

Finally, the greater satisfaction and range of use to be had in a car of good value is not usually estimated for what it is worth. A cheap car, for illustration, may well answer all purposes for driving on smooth roads or in city streets, but it may be totally unfit for driving on rough roads and for long tours in the country. Just how much a car of this sort lacks in adaptation to the requirements of the owner of course depends upon circumstances, but it is well to consider facts of this kind in making a purchase, as well as likewise just how much individual feelings are affected by owning a car that is known to be of inferior quality and that is sure to be passed by every other car on the road when it comes to a good stiff grade.

THE CYCLECAR COLLAPSE.

A writer in Printers' Ink attempts to give the moral—or to use a popular but perhaps less correct word—the "psychology" of the cyclecar boom and its collapse.

He first shows how this boom went up like a rocket and came down like a stick, and then gives the reason for it. He adds that he knows personally of one warehouse that contains a half million dollars' worth of unassembled cyclecar parts, and sums up the reason therefore as follows:

"The costly failure of a whole industry is attributable to one fact: The cyclecar was absolutely out of joint with an equally well advertised and consequently well-known personal transportation market."

What he means, we suppose, is that in view of other well-advertised and satisfactory automobiles at a low price there was no market for an innovation that was not considered as attractive. But there was another reason for the temporary—possibly the permanent—failure of the cyclecar. In cases where its design and construction were correct and it would have met a well-defined public need, it was not handled in a judicious way and where it was handled judiciously it did not meet the public need.

The original idea of the cyclecar was the correct one. This was something far lighter in weight than the regular automobile runabout, and consequently a car that could be run and stored at less expense. With these requirements achieved it did not matter much whether the price was a little more or a little less than that of the low-priced cars of the regulation pattern and use.

Of course there is but one way to secure the essential light weight and the necessary strength and stability, the tread must be made much narrower and the standard of 56 or 58 inches. We believe it might be as narrow as 30 inches. To prevent overturning with such a narrow tread, it would be necessary to use wheels of large diameter, say 38 or 40 inches, and by underslung construction obviate its liability to overturn. Of course this narrow tread would enforce tandem seating for which there was some objection on the part of the public. Yet there is a certain per cent. of tandem seating in all vehicles where there is more than one seat.

But construction of this sort would practically reduce the weight of the car one-half, it would reduce the tire wear one-half, the lubricating oil one-half, the storage charge one-half and the repair bills

Digitized by Google

practically one-half. This having been accomplished the automobile would be within the means of a large class who do not now feel they can afford it solely on account of its expensive up-keep. Quite likely this class is as large as the entire class who already own automobiles.

As to the price of the cyclecar, it matters little whether it be more or less than the cheap standard runabout. The main thing for consideration is the cost of up-keep. Between a maintenance cost of $20 a month and $10 a month, there is a difference of $120 a year, or the interest on an investment of $2,400 at 5 per cent.

There has been and will be a demand for a cyclecar built according to the foregoing outline. Any manufacturer who will perfect it and cleave to it, despite the slight objections and difficulties experienced by all who leave the beaten paths, will find a large market ready to purchase it.

IT ALL DEPENDS.

The automobile is like truth—"it needs no ornament." It is at once so useful, so economical, so convenient and so cheap in price as compared to its value that it requires no special plea or favor.

But when some one claims that it is a safer unit of travel than the horse-drawn vehicle he is stating something that car owners and drivers know is not in accordance with the fact. What we mean is that it is not safer when used by the average man but it can be used in such a way that it is much less dangerous than the horse-drawn vehicle with the horse attached. The freedom from accident by the automobile depends wholly and invariably upon care and skill in driving. The freedom from accident by horse driving often depends upon the horse and not the driver; in case of the car it depends upon the person driving it.

But the startling and disquieting fact in relation to careless automobile driving is that it is increasing. Possibly this increase may not be out of proportion to the increase in use of the automobile, but it should be less; the reckless are fast being put out of the question by maiming or death, and this might not be so extremely regrettable except that they are likely to kill or maim the careful users of the automobile, along with their own undoing. This being the situation, we see no method of treating the matter save by continued admonition and warning.

Take this State and city of New York, for illustration: According to figures compiled from the report of the National Highways Protective Society, the fatalities due to automobiles in New York State, including New York city, for the first six months of the present year, increased from 183 for the corresponding period of the year 1914 to 241. In New Jersey during the same months automobiles killed eighty-eight persons, as compared with forty-eight in the first six months of 1914.

In New York State, outside the city, during the last month thirty-six persons were killed by automobiles, seven by trolleys and three by wagons.

In New Jersey during the same period forty persons were killed by automobiles, four by trolleys and three by wagons. This is the greatest number of automobile fatalities in any one month in that State.

In New York city more arrests have been made for speeding than ever before. There have been about four thousand this year, but the offenders seem content to pay the fine imposed and do not hesitate to repeat the offence with impunity, though the magistrates are imposing minimum fines of $25 for the most part. It would help to reduce the evil if maximum imprisonment were substituted for minimum fines.

AFTER A CAR IS SOLD.

Some of the automobile manufacturers are waking up to the advisability of taking better care of the purchasers of their cars after they have been delivered. There is need of it. Indifference in the past seems to have been the rule rather than the exception, although the fault may have been due as much to the selling agent as to the manufacturer.

The average automobile purchaser injures his car during its first two or three months of use far more through ignorance than anything else, but this ignorance might be avoided if the purchaser were given the careful instructions and the general oversight to which a purchase of this magnitude is entitled. Such instruction and oversight on the part of the manufacturer or salesman are both good business policy and good business principle.

What to the demonstrator or the salesman may seem to go without saying, or be assumed without thought or consideration, may need impressing upon the purchaser again and again. Facts or knowledge which to the experienced driver may be instinctive are likely to be overlooked by the novice who has quite a number of things to bear in mind at the outset. Most of us can carry two or three new things in mind quite readily but when the number is multiplied by two or three something is likely to be forgotten and that forgotten thing may be of the utmost importance.

A dissatisfied purchaser is not a good advertisement for any car, and a badly running car or one undergoing repair by the roadside often creates a wrong impression. Either is liable to interfere with future sales.

Practically the same situation exists in relation to repair parts or replacements. The owner of a car values, at far more than its cost to the manufacturer, the ability to get repairs or replacements promptly. But the car owner often assumes a somewhat unfair attitude in relation to the cost of some simple part. It may not cost to produce it, any more than it costs to manufacture a stock bolt or tool that is of general utility, and which is on sale at every hardware store, and he often expects to pay no more for such parts. But of course this is unreasonable. He goes to the hardware store for a common bolt and the clerk hands it out to him as he does to many others. But in the case of the special automobile bolt or part he sends for it by mail; the clerk for the manufacturer goes to the stock room to get it, wraps it up, addresses it and it is forwarded by mail or express. It is thus easy to see there is little comparison between selling articles of general use over the counter and forwarding articles of limited use by mail or express, as stated.

It is a question solely for the automobile manufacturer to decide as to whether he should sell such small parts at cost or less than cost and thus please his patron and possibly gain a "booster" for his firm and his car, or make a purely business cost-and-

Digitized by Google

profit transaction out of it, and perhaps thus create a "knocker."

In our opinion, the manufacturer, in consonance with good business policy, should sell parts or replacements at the lowest possible price. We have in mind one firm—not an automobile manufacturer—which makes a very large profit from the selling of replaced parts to the machines they manufacture. But this refers to a machine of far less universal use than the automobile. Possibly in this case their policy may be a good one, although they rest under the imputation, just or unjust, of purposely making parts of poor quality so that they must be renewed frequently.

THE RATIONALE OF SOUND.

Automobile signals should be loud enough to attract the attention of the somnolent as well as the alert, and it is astonishing how many of the first-named may be found in the public highways and streets. To do this invariably, a lullaby is ineffective. The signal should be as striking and forceful as is necessary to meet the desired purpose. Yet it is well enough to understand that it is a mistake to imagine such a signal is only for the protection of the driver using it. If self-protection were the only reason for a law requiring such signals to be used, such a statute would not nor should not have been enacted. It is not the business of the State to protect individuals against themselves but against others.

Many seem to imagine that the signal means, "Get out of the way; I'm coming." It means nothing of the sort. One person or vehicle has as much right to occupy the highways as another. The strongest and swiftest vehicle has a far greater responsibility than the weakest and slowest. The strong and swift almost invariably act upon others, while the slow and weak are as invariably the objects of such acts.

But that matter need not be gone into here. The important fact is that a warning automobile signal should be loud enough and startling enough to invariably attract the attention of those whom it is intended to warn. The quality of the sound has nothing to do with it, one way or another. The screech of a locomotive whistle is not pleasant to the ear, but as it is necessary no one is inclined to find fault with it.

In fact, no necessary sound is offensive to rational and reasonable ears, while any sound whatever that is unnecessary may be offensive. The hum or clatter of machinery, for illustration, means industry—the performance of duty and of necessity—and no one has a right to object to it. If it be offensive, let the offended take himself away from it and not expect that the sound to be taken away from him.

The ringing of church bells is no longer necessary, and consequently this sound may be objectionable. It was instituted when there were few clocks or watches in order to indicate that it was time for public worship to begin. But now that clocks and watches are about as free as water and as common as air, clanging church bells ought to be prohibited. They are often positively harmful to the sick, and there is no more reason why church-goers should be notified that it is worship time than theatre-goers should be notified that it is theatre time.

Although fire alarm bells are louder than church bells, no one has a right to object to them, for they serve a useful purpose in the smaller cities and towns. So likewise, a loud voice is not objectionable when addressing a deaf man, but when addressed to one who has good ears it is decidedly offensive. A loud voice in the pulpit or on the platform is necessary; when used in the home a well-modulated voice—which can be easily cultivated—is the only sort of a voice that should be borne without protest. The whistle of a boy when out-of-doors, and "for want of thought," is pleasing. The same whistle in a business office should cause him to be impelled through the door or window.

Thus it will be seen that sound has its time and place. An automobile signal sounded unnecessarily is an abomination, but at the proper time and place no one has a right to object to it, and its quality must be that which will best answer the purpose for which it is desired.

AHEAD IN EXPORTS.

False impressions are as thick as "leaves of Vallombrosa." Often they are acquired through correct information, but no note is taken of a change in conditions or facts, and soon we are confronted with contrary statements which we do not readily credit.

For instance, it is the prevailing opinion that the exports of this country to South America are a mere bagetelle compared to those of Germany and Great Britain. On the contrary, the United States exports more merchandise to South America than does any other nation. To-day, of course, we export to the Latin-American countries far more than both England and Germany, but our exports exceeded either before the war began. For the year 1913, the latest year upon which figures are available, the exports to South America from the United States were $325,837,345; from Germany, $217,967,202; from Great Britain and Ireland, $322,228,073.

It may be remarked that the export trade of Great Britain has been acquired by high quality and durability, that of the United States by improvements in construction and lightness as well as gracefulness, and that of Germany by cheapness and often at the expense of quality.

UNJUST CHARGES.

There is a crying need here in the East for some good country hotels for automobile tourists in which wholesome and well-prepared food is served, where there is no flunkeyism, and where old-fashioned hotel hospitality abounds at fair prices.

When a man and his wife with a car are charged from $8 to $10 for a night's entertainment, including supper and breakfast, it is altogether unreasonable. There seems to be a feeling in many such hostelries that every man who drives an automobile is a Croesus, and that as he is liable never to see him again, it behooves the doughty "innkeeper" to relieve him of as much cash as possible. We have found that as a rule it is wise to keep out of "inns." Just a plain every-day hotel is good enough, and if there were any in these "up-to-the-minute" days, just a plain old-fashioned tavern would be attractive.

And the same situation prevails in relation to garage and repair places in the country districts. The writer of this has paid 25 cents for making a simple adjustment of a spark plug in one case, and

Digitized by Google

$1 in another instance for doing absolutely the same thing. In either case a pair of pliers and three minutes' time was all that was necessary to do the job. In passing it may be remarked that it is well to renew a pair of pliers the moment they have been lost or stolen.

Evils of the sort mentioned are not invariable, but they are so common that it is hoped their victims will not shrink from mentioning them.

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

While Racing with a Train.—Two persons were killed and six injured at Columbus, Ga., when an automobile which was being raced with a train was struck squarely in the middle by the locomotive at a crossing. It was hurled 300 feet and totally destroyed. Some of the passengers were thrown so far that they received little injury except bruises and cuts, but two were killed and another probably fatally hurt.

Kills a New Owner.—A man was instantly killed at Caro, Mich., while driving a new automobile across a bridge. He seems to have lost his head and in some way the car speeded up, going from one side of the road to the other until it upset. The victim's neck was broken.

Crashed Through a Barn.—A farmer near Holland, Mich., met instant death when he lost control of his car and it dashed through the side of the barn. It fell some 15 feet to the ground on the other side of the barn and broke the neck of one of the occupants. The other escape with little injury.

Three Men Hurt.—Near Saginaw, Mich., a car struck a hole at the end of a bridge and the driver lost control. It was traveling about 25 mies an hour, and when it left the road it crashed into a telephone pole, snapping it off and turning over three times into a deep ditch. It was completely wrecked and three men were very seriously injured.

May Be Crippled for Life.—While running at a slow rate of speed near Meadville, Pa., a car got too close to the edge of the road and went down over an embankment. Two women and a boy were in the car and they were all very much injured. One young woman may be crippled for life.

The Ubiquitous Cow.—In trying to avoid a cow in the road, which was being led by a farmer, the driver of a car went into a deep ditch, at St. Johns, Mich., and was suddenly killed. The farmer was unable to move the cow from the center of the road. Balky cows are of common occurrence, although probably they have no intention of being recalcitrant.

A New Oiled Road.—Near Watertown, N. Y., a driver of a car failed to see a sharp turn in time to diminish the speed of the car. The newly oiled road caused the machine to skid and it soon turned completely over pinning one young woman beneath it. It almost severed an ear from her head and she was otherwise bruised and injured.

Stalled on the Street Car Tracks.—At Waukegan, Ill.. a big touring car became stalled on the electric railroad when a street car was approaching at high speed. The adult passengers were able to leave the car and the children were tossed upon the ground. The collision was terrific and the touring car was damaged beyond repair, but there was little personal injury.

One Dead and Four Hurt.—A car struck a post on one side of a bridge over a railway track at Echo Lake, Pa., glanced off and plunged through a fence. It overturned and pinned the occupants under it, 25 feet below the road. The owner of the car was killed and the four passengers all more or less injured. The chauffeur jumped from the car and sustained only slight bruises.

Result of Lack of Attention.—Near Warsaw, Ind., two women were injured when their automobile rolled down a steep embankment. One of the women pointed to the spot where shortly before two people were killed, and the driver turned to look and his machine rolled over the bank and landed in the same spot.

Lights Fail on Dangerous Curve.—One man was killed and three injured near Medford, Oregon, when an automobile going forty miles an hour plunged down a steep embankment into a ditch. The accident occurred when the electric headlights on the car went out suddenly while it was rounding a treacherous curve. One man was thrown out and received a fractured skull and jaw from which he died, and the others were injured but will recover.

Defective Control.—One man was killed and another badly injured near East Peoria, Ill., when the driver lost control of the car and it ran wild and turned turtle in the ditch. One man was caught under the car and crushed and the other was thrown to one side. It is said that the steering gear was not working properly when the machine was purchased and was remedied temporarily at a garage only to again develop.

Turned His Head for Instructions.—A man and woman were killed at White Plains, N. Y., and another woman injured when the driver dashed around a curve and went down a 25-foot embankment. The woman received a broken neck and arms and the man's skull was fractured. It is stated that they were driving on an unfamiliar road and the driver turned his head for instructions from the lady, who was directing him from a map, and thus failed to see the sharp curve in the road.

Speeding in Dense Smoke.—Three persons were badly injured near Tulare, Cal., when two machines going at the rate of 30 miles an hour, entered a dense smoke, caused by grass fire from opposite sides, and crashed in a head-on collision.

Turned Too Quick.—A man was instantly killed near Sheridan, Mich., when his automobile went over the bridge into the river. The car was descending a hill at the foot of which was a bridge and when he reached the bend to the approach he turned too quick and sent his car over the embankment and was thrown from the machine with a force that broke his neck.

Struck a Dog and Overturned.—One boy was killed outright and the driver of a car died soon after an accident which occurred at Sacred Heart, Minn., when a car carrying seven passengers struck a dog and overturned. The other occupants of the car were injured.

Due to Reckless Driving.—Near White River Junction, Vt., a young man was killed and three of his companions badly injured when the heavy machine in which they were riding struck a bridge head-on and turned completely over. The occupants

Digitized by Google

were thrown from the car and the rear wheel struck one young man, killing him instantly. So great was the impact of the car with the bridge that the engine and radiator were driven back under the front seat. It is stated that before the accident occurred the driver had been reproached by the passengers for his reckless driving and had asked him to let them out but he still continued his terrific pace.

Loses Control of Car.—In an effort to avoid striking a wagon which was approaching, in Johnston, Pa., a young woman lost control of the car she was driving and it struck a telephone pole, swerved to the right and crashed through an iron fence on the top of a retaining wall. The fence gave way and the car dropped ten feet to the street below. A young woman companion was pinned beneath, striking on the back of the skull and killing her instantly. The driver was uninjured.

Result of a Tire Explosion.—At Missoula, Mont., a girl was killed when a tire burst and the car overturned. Although the car was traveling at a moderate speed the sudden collapse of the tire cramped the front wheels and the steering gear snapped. The car plunged into a ditch and turned over. One young woman was killed and several were injured.

AUTOMOBILE ROUND-TABLE.

A New Idea for a Garage That Promises to Result in a Good Investment.

From G. D. Crain, Jr., Kentucky.—For the purpose of supplying storage and maintenance facilities to owners who are either too far from a regular garage or feel that the charges involved in their use are prohibitive, a new kind of garage has been evolved in a number of cities. The one to be described is located in Louisville, Ky.

The building is of concrete blocks, and is divided into eight separate, partitioned stalls for the reception of individual cars. The partitions are of 6-inch hollow tile. Each stall is equipped with electric lights and water, with a drain, and there is sufficient room to enable the owner to carry oil, tools and various supplies. In the winter the building is heated, connection usually being made with the heating plant of some nearby apartment house.

The building in question cost $1,400, and the gross income at $10 a month for each stall, is $960 a year. Taking off the necessary charges for light, water and heat, it is evident that there is enough left in the way of income to make the owner feel that he has a very good investment, especially as alley property, which would not be available for high-grade buildings of any other kind, is used. On the other hand, the autoist who leases a stall in an "automatic" garage of this kind gets good quarters, fireproof—even the roof is of concrete—and facilities for taking care of his machine at a cost which is not excessive.

Altogether, it looks as if there is room for a goodly number of such establishments in every city, especially in the suburban districts where garage service of the usual sort is not always available.

Safety First in Garages.

The report of a fire which not only destroyed the garage in which it was located, but all of the motor cars it contained, as well as several buildings adjoining, included the following paragraph:

"The fire was caused by a spark from a machine which Mr. Brents was preparing to take out of the building, igniting gasoline which had leaked on the floor from another machine. Mr. Brents, in trying to save the machine, narrowly escaped serious injury."

Carelessness about allowing gasoline to leak over the garage floor, in not cleaning up oil drippings, and in not disposing of oily waste and other dangerous refuse in metal containers, usually has a sequel something like the one referred to above. And inasmuch as automobile owners and other property-owners are likely to suffer, as much as the garage man himself, he owes it to the public to adopt every safeguard that offers itself.

The Touring Car That Stays at Home.

The automobile was introduced under conditions which evolved appellations which the current use of motor cars does not justify. Take "touring-car", for instance; would you call a five-passenger automobile, being driven by a contractor, who is incidentally hauling several hundred feet of hardwood flooring in the machine, and who is on his way to lay down the material in a suburban residence, a touring-car? That is what it is called, but the name does not suggest the service it is performing in the slightest degree.

Many an electric contractor and plumber have solved the problem of getting both men and material on the job quickly and easily by the use of a car larger than a runabout. The men are carried on the seats, and the material is scattered about on the floor, or tied onto the running-board, and perhaps stowed away between the fender and the hood.

The "touring-car" of high degree, which was purchased exclusively for pleasure, and spent most of its time on the broad highway, would probably have resented being put to such plebeian and everyday uses; and the business men who are using automobiles for this purpose are admirers of the touring-car for entirely different reasons from those which animated the first purchasers.

The Dealer and His Customer.

The other day an owner drove into a garage, where he was accustomed to have repairs and adjustments attended to, and told the proprietor about an unpleasant noise which the car made at speed above 30 miles an hour.

The dealer made an investigation and drove the car a short distance himself, later reporting to the owner that the trouble was caused by worn push-rods.

"I don't believe I'd do anything about that just now," he advised. "We would have to spend a good deal of time making the change, and the new parts would cost considerable. As long as the operation of the car is not interfered with, and the noise occurs only at a rate of speed which you do not frequently use, I believe I'd let it go until you have a general overhauling made, when the matter can be fixed up with much less expense."

Apart from the question of the correctness of the prescription in this individual case, there is no doubt that one of the reasons for the popularity of this dealer, and the way his customers stick to him, is that he never tries to force a job. If the work isn't really needed, he tells the customer so, and the latter realizes that the dealer is working for his interest as well as his own. That sort of attitude, the desire to be helpful, and not simply to make money out of

Digitized by Google

the customer, is the sure way to make friends and permanent patronage for any kind of establishment, from a garage to a department store.

Arrangement of Curb Fixtures.

The garage which installs a gasoline station and an air compressor ought to have these arranged at the curb so that there will be as little congestion as possible among the automobiles which make use of them. Now and then one finds an instance of poor arrangement which so limits the number of those who can get gasoline and air as to seriously handicap the business. Sometimes a car which stops to get air will block the way to the gasoline tank, and vice versa, the result being that a great many customers pass on to the next station because of the delay that is involved.

In this connection it is worth noting that speed in handling gasoline sales has a lot to do with the volume of business taken care of. Inasmuch as the heavy end of the trade develops on Saturdays, Sundays and other special occasions, there is bound to be some kind of tie-up unless special provision is made to prevent it. One big dealer found that it paid him to replace one small gasoline pump with two larger ones, the latter being equipped with features which enabled the fluid to be dispensed much more rapidly than with the old fixture.

Moral Hazard of Autos.

Insurance companies are devoting a good deal of attention to the "moral hazard" connected with writing automobile policies covering fire, theft and various other casualties. The opportunity, or at least the possibility, of fraud and deception entering into the situation has been the subject of considerable discussion. The following suggestions of an automobile underwriter have been submitted to the companies:

"The name and address of every assured having an automobile loss should be reported to the companies, with the data regarding the nature of the loss. This would give a much needed line of information on the rapidly increasing moral hazard surrounding theft losses. There is a growing practice among certain classes of automobilists carrying theft insurance to report the loss of extra tires from their machines when they need a new set, as they would rather have the company pay for them than do so themselves. There is no possible way of establishing losses of this sort, and the word of the assured must be taken in every case.

"There is also an increasing practice of burning a car which has begun to show signs of wear, in order to obtain a new one without extra cost. Investigation of a number of claims shows cases where this method has been consistently practised by some assured. It is probable that in the great mass of detail handled by the companies this fact is being overlooked, but proper reports and checking up of automobile policies would perform the same function that the mercantile agency does for the fire insurance business, and it would seem that such a practice is equally as important to automobile writing companies."

To offset the latter statement, however, it should be recalled that the companies have a regular schedule of values at which automobiles are written, and it is usually well within the market value of the car of a given year. Consequently limiting the amounts written would seem to eliminate whatever moral hazard might be inherent, assuming, of course, that the correct model of the car were furnished to the agent. If it were found, after a loss, to be incorrect, the policy would be invalidated.

Burglar Alarm for the Garage.

This device is so constructed, as to give warning to the car owner in his home, whenever a burglar enters the garage, if by the window or door. In Fig. 1 is a diagram showing the device in use on the

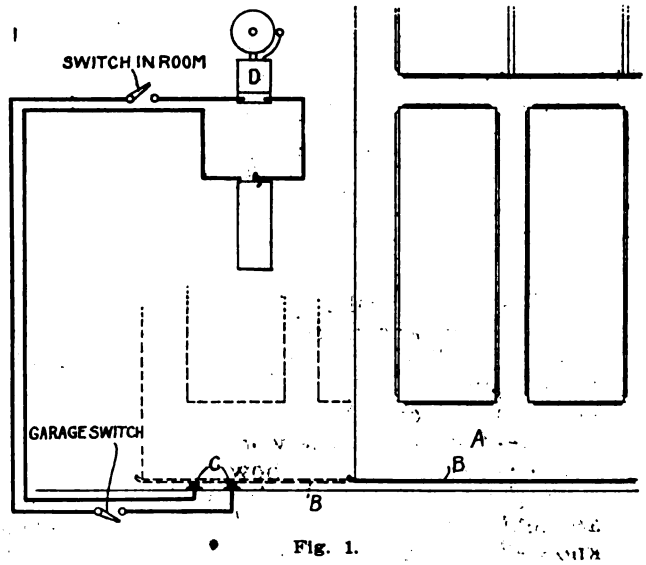

Fig. 1.

door. The door A, has a copper strip, B, screwed to the bottom, and extending the entire length of the door. When the door is opened this strip comes in contact with two copper posts C, and makes a direct electric current, and by doing so rings the bell which has a white letter D, painted on it. This indicates the burglar is entering through the door. In

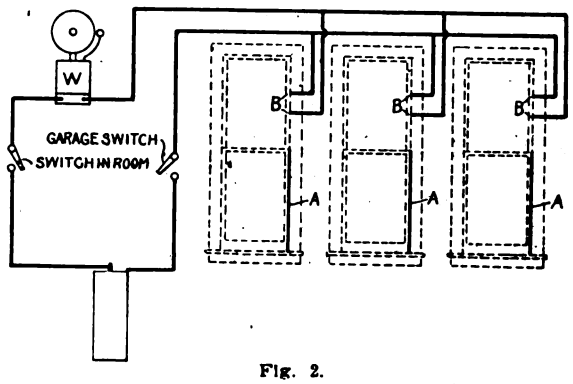

Fig. 2.

Fig. 2, is shown the diagram of the wiring of the windows, the operation being the same as the door. By raising the window the metal strip A, comes in contact with the copper posts B, making a direct current and ringing the bell with a white letter W, painted on the same, to indicate that the burglar is entering through the window. Both bells can be placed in the bedroom. By the slightest move of the windows, or doors, the signal is given, and the owner knows where to locate the intruder. There are two switches in the device in Figs. 1 and 2, to be let open when at work in the garage and closed when leaving.

WORK OF CHAUFFEURS.

An Open Letter of Advice to Them by a Well-Known Physician.

Dr. A. F. Currier, a physician employed on the staff of the New York Globe, recently published in that newspaper an open letter to chauffeurs in which he said:

"There are many dangers connected with this business, and it is strange that where there are so many reckless and ignorant and stupid drivers, broken necks and broken homes have not been more numerous. It would appear to go without saying that a good chauffeur must be a good mechanic. He ought to know an automobile from A to Z, blindfolded or on a dark night; and as so much good brains is necessary to keep a complicated piece of fine machinery—which a fine car really is—in good condition, I cannot help wondering at the nerve of some men who call themselves chauffeurs and think they are competent to do this.

"I hope the legal requirements for a license will become more and more exacting, for that will be a long step in the way of getting a more highly trained class of chauffeurs. It ought not to be necessary to say that the chauffeur should be one of the most level-headed men in the world—like the engineer on a passenger train; yet how often you see a man driving a car who is so intoxicated that when an accident occurs he is incapable of using even such knowledge as he may have or of doing any mental work in the interest of his passengers and his car. It is equally necessary that his hands should be steady; yet I have seen plenty of chauffeurs who were cigarette fiends to such an extent that their hands were constantly trembling. I have been also told that many chauffeurs are victims of 'dope,' which is the very last thing they should touch.

"I would lay down as a cardinal rule for you that you totally abstain from alcohol and opium in every form and on every occasion; and because the cigarette is so seductive you would be far safer if you foreswore it altogether.

"But you will say, What is a fellow to do after he has had a long run—perhaps has been up most of the night and is wet and cold? Well, he does need something hot, and he ought to change his clothes and take a warm bath if he can; but he does not need whiskey or any other form of alcohol. Hot coffee will stimulate and stir him up far better, and diminish the chances of pneumonia.

"Many times the question has been asked whether the constant motion in a car is likely to cause displacement of the organs of the body. In case the car is not well protected with springs, or in the case of cars which travel over very rough country roads, I have no doubt this danger exists and that the stomach, intestines, liver and kidneys are sometimes displaced; but probably not more frequently than by the jolting of wagons over rough roads.

"The care of the eyes is a matter you are very apt to neglect, and it is of such importance that I feel you ought to be urgently cautioned about it. It does not seem to me that ordinary driving is any worse for the eyes than is driving in a carriage; but if you are going hard against the wind and the air is full of dirt and cinders, you can easily damage your eyes for the time, or even permanently. I would advise you, therefore, always to have goggles in your pocket, ready for prompt use.

"Riding fast against the wind sometimes develops pneumonia and other lung troubles. You ought to have your chest well protected always, and breathe through your nose. If you can't breathe with perfect ease in this way you should have your nose treated by a competent physician until you can.

"I suppose a majority of chauffeurs acquire the speed habit. It is natural, perhaps, as you ride along in safety day after day to accelerate almost unconsciously; but this is the first step to racing—and racing with automobiles is dangerous, very dangerous.

"It appears to me this is one of the things against which a good and steady chauffeur ought to be constantly disciplining himself. Your value depends on your intelligence and your skill. If you have the reputation of being dependable and ready for emergencies, I can think of no occupation which holds out much greater inducement to a thrifty man. And if you are careful always to preserve your health and your faculties, you are pretty sure of steady work throughout the working period of life."

THE LEGAL ASPECT.

Cases in Court That Point a Moral to Car Owners and Drivers.

Relation of Master and Servant between Driver and Owner of Automobile.—In an action for personal injuries, caused by being run into in a street in Providence, R. I., by the defendant's automobile, while it was being driven by one Angell, who was its only occupant at the time, the defendant denied that Angell was in his employ. Evidence for the defendant established the following facts: After the defendant bought the car he arranged with the directors of a Rhode Island corporation, operating mills at Greystone, in that state, of whom he was one, that the car should be maintained and its running expenses paid by the corporation; that it was thereafter used for the convenience of the corporation and its officers; that Angell was engaged by the directors to drive it soon after it was purchased, and he did drive it for four or five weeks thereafter; and that Angell was paid by the defendant, but out of the corporation's funds. The defendant lived in England; most of the stock in the corporation belonged to him or members of his family; he was its president and treasurer; he had come to Rhode Island with some of his family not long before the accident, and returned to England with them soon after it. While here he lived at a hotel in Providence. He bought the car because he wanted to go in it to and from the mills, the bank, etc. It was agreed upon as fair, between him and the other directors, that he should use the car to take his family about when it was not in use for the corporation, and it was used, while Angell drove it, sometimes for the purpose of the corporation, and sometimes when not so used, by him or his family for other purposes. It was held that his ownership of the car and Angell's general employment as his servant for the special purpose of operating it, at least warranted the inference that Angell was running it as his servant at the time in question, in the absence of evidence to the contrary. If, as a matter of fact, Angell was not then so running it, the fact

Digitized by Google

should be peculiarly within the defendant's knowledge and the burden was on him to establish it. The question whether the car was being used at the time for the corporation's purposes or for his own private purposes, or by Angell for purposes authorized by neither, was for the jury.—Benn v. Forrest, C. C. A., 213 Fed. 763.

Collision on Private Street Railway Right of Way.—The Pennsylvania Supreme Court holds that where a street railway company operates a double line of tracks upon its one private right of way in the center of a public highway, above the level of the road and protected by a stone curb, it is not liable for injury to an automobile struck by a car while on the tracks at a point where there is no crossing. In its final analysis, the case was held to turn on the answer to the inquiry whether the testimony would sustain a finding by the jury, that the motorman had knowledge, or by the exercise of proper car would have known that the plaintiff's automobile was on the track in time to avoid injury to it. The case was a close one, but judgment for the defendant was affirmed.—Taylor v. Philadelphia Rapid Transit Co., 91 Atl. 631.

Evidence as to Depreciation in Value of Damaged Automobile.—In an action to recover damages for injuries to an automobile resulting in a collision, it was held that where the plaintiff has shown the cost and the expense of putting the machine in good condition, and the amount that he had spent for the use of another machine while his own was being repaired, he cannot be permitted to show by non-expert testimony that a motor car, after a collision, depreciates twenty-five per cent. in value, by reason of the collision. All persons do not have every day experience enabling them to testify as to the construction and repairs of automobiles. Nor do they have such experience enabling them to estimate the percentage of depreciation caused to an automobile by a collision, after the machine has been fully repaired and put in operation.—Stevens v. Adams Express Co., 55 Pennsylvania Superior Ct., 366.

Collision with Street Car at Crossing and Questions of Negligence for the Jury.—In an action to recover damages for injuries to an automobile, the following facts were shown by the evidence: The automobile approached a crossing at the rate of six miles per hour. The chauffeur looked and listened and saw an electric car about 160 feet from him as he neared the tracks. The machine did not take its gas as fast as it should and was struck before it cleared the tracks by the street car, which was going at a rate of thirty to thirty-five miles an hour. The automobile was hurled by the car eighteen feet along the tracks. It was held that the question of the Motorman's negligence and the chauffeur's contributory negligence was for the jury. A pedestrian or person about to cross the street, at a regular crossing, is not bound to wait simply because a car is in sight. If it is at such a distance from him, that he has reasonably ample time to cross, if it is run at its usual rate of speed, it cannot be said, as a matter of law, that he is negligent in going on. Judgment for the plaintiff was affirmed.—Dickley v. Southern Pennsylvania Traction Co., 56 Pennsylvania Superior Ct., 113.

Acts in Emergencies.—The driver of a horse, under the belief that a collision was imminent with an automobile 75 feet behind, jerked suddenly on the reins, causing the horse to fall. There was no misconduct on the part of the chauffeur, reasonably calculated to cause a belief that such action was necessary to prevent a collision, and it appeared that the owner of the horse was unreasonably frightened without cause. It was held that the owner of the automobile was not liable for the value of the horse.—Carter v. Walker, Texas Civil Appeals, 165 S. W. 483.

Evidence of Indemnity Insurance Inadmissible.—In an action for personal injuries from being run down by an automobile, through the alleged negligence of the defendant's chauffeur, it was held that the admission of testimony by the defendant on cross examination, tending to show that counsel appearing for him represented an indemnity insurance company, was error. The defendant's liability would not be affected by the fact that he was indemnified, nor did it affect his credibility.—Watson v. Adams, Alabama Supreme Court, 65 So. 528.

Injury to Automobile Passenger on Street Railway Track.—The driver of an automobile was trying to start his machine, which was stalled on a street railway track. A passenger in the automobile saw a street car approaching when it was 600 feet away; but, as the stalled automobile was in plain sight of the motorman, he thought it would stop and paid no more attention to it. The automobile was seen by the motorman when 600 feet distant, but he did not attempt to stop until it was too late, the car dashing into the automobile and seriously injuring the passenger. In an action for his injuries it was held that the general rule that no one need have warning of an approaching danger, which he sees did not apply here. The court properly submitted to the jury whether the failure to sound or give warning was the proximate cause of the accident, since, if the gong had been sounded, it would have notified the plaintiff that the car would not stop, and he probably could have leaped from the automobile.—Peterson v. United Rys. Co. of St. Louis, (Mo.), 168 S. W. 254.

Rights of Occupants of Unregistered Automobiles.—In Massachusetts, differing from the rule elsewhere, it is held that the occupants of an automobile which has not been registered according to law, are trespassers on the highway, and have no rights against other travelers, except to be protected from reckless or wanton injury. In an action for injuries received in a collision between an automobile and an electric street car, it was held that the defendant had the burden of proving that the automobile was not registered by law at the time of the accident—Dean v. Boston Elevated Ry. Co., Massachusetts Supreme Court, 105 N. E., 616.

Liability for Injury to Unregistered Automobiles.—In an action for injuries to an automobile caused by collision with one of the defendant's street cars, it is held by the Alabama courts to be immaterial to the defendant whether the automobile was or was not registered in compliance with the laws of the state, which required all automobiles to be registered. If the automobile was not registered, the owner might be guilty of a violation of one of the criminal laws of the state, but that fact in no way affected the general duty, which the defendant owed to the law, to so operate its cars as not to negligently injure the person or property of any person. The mere fact that the automobile was not registered had no

Digitized by Google

casual connection whatever with the injury of which the plaintiff complained, and that fact in no way contributed to the injury to the automobile.—Birmingham Ry. Light & Power Co. v. Aetna Accident & Liability Co., Alabama Supreme Court, 64 So. 44.

Care Required Under Missouri Statute.—Action was brought for personal injuries caused by being run down by the defendant's automobile, which was being taken home in a damaged condition by his chauffeur, in obedience to his orders. The tire of the left front wheel had been taken off, owing to a puncture, and the wheel was running on the rim. The steering gear was worn. The chauffeur admitted that he saw the plaintiff in a reasonably sufficient time to have warned her or to have stopped his machine before striking her, and he said he did warn her, but did not stop. It was held that under Missouri Rev. St., 1909, ss. 8523, requiring persons operating automobiles along public streets to use the "highest degree of care of a careful person," to avoid injury to pedestrians, a chauffeur approaching a woman walking in the street ahead of him is required to stop to avoid striking her if he has an opportunity to do so and if he cannot safely pass her. Judgment for the plaintiff was rendered on account of the erroneous exclusion of evidence for the defendant regarding the cause and extent of the plaintiff's injuries.—Porter v. Hetherington, (Mo.), 158 S. W. 469.

Improving the Ford Car.

From N. G. Near, New York.—I have often wondered whether or not it pays to equip a Ford car with the many accessories made expressly for the Ford, and so I sought out two owners who have done about all they can do in changing such cars into something entirely different. They have different carburetors, piston rings, ignition systems, spark plugs, shock absorbers and other additions and attachments. If the Ford can be improved, I thought, these men should be able to tell me.

The first man I asked said, "Take it from me, if you buy a Ford, leave it just as it is. Don't change or add a thing. Every time I make a change my car seems to do better for a while, but in time it is worse than ever, and when I run it into a Ford repair shop the repairman blames the 'new device.'" I then asked this man if he was much of a mechanic himself. His reply was, "No, I tinker around a whole lot, but when it comes to making really fine adjustments and doing the vital work I am not there. I am dependent upon the shop repairmen."

The second man's story was entirely different. He found that most of his changes had proved beneficial. The addition of a more expensive and better carburetor and the installation of leak tight piston rings saved gasoline; the ignition system was better; the spark plugs better; and so on down the line.

"Do you do your own repairing, cleaning and adjusting?" I asked. "Yes, every bit of it. I am a mechanic, have a good shop in my garage and seldom need outside aid at all."

To me these replies seem logical and conclusive. Some men can actually better the Ford car. Others cannot do so. It all depends upon the man or the repairman to whom the owner entrusts his car. I do not doubt but that some and perhaps most repairmen give their patrons a "square deal." In other instances, as above, the owner is entirely at the mercy of a crooked repairman unless he himself is an expert mechanic.

PROOF OF IMPROVEMENT.

Mr. Near Comes to the Defense of His Coasting Test.

From N. G. Near, New York.—With reference to F. L. Angier's criticism of my contribution on "The Coasting Test," I wish to say a word about his statement, "the amount of work done on the motor and transmission in taking up the various parts, should have put the motor in such shape that when attempting to coast with the clutch engaged, if the rings were properly fitted and the valves were properly timed and ground it should not have coasted as far."

I do not doubt but that I would have been discharged had I been working on a regular commercial basis because I took special pains with this test car and consumed considerable time just to prove my point. It is well known that cars are usually "tight" immediately after overhauling because bearings are taken up just a little "too much," pistons are "too tight" and rings may be a little too tight. However, when they are all fixed "just right" there will be less friction than before, save in the cylinders.

In the cylinders, though, we have a rather peculiar condition to contend with, namely, by creating more friction and better compression at the same time it is possible to save power, in which case the car will coast farther. But, should this friction be great, as experienced by Mr. Angier, power will undoubtedly be lost and the car will not coast so far.

In cranking a car by hand it feels more difficult with good compression than with poor compression, and it is more difficult up to a certain speed. What that speed is depends entirely upon the condition of the engine. If a flywheel is placed upon the shaft the difference in power requirements is more easily felt, for the retarding force of compression is eliminated after the flywheel is well started. In a coasting automobile the car itself serves as a flywheel.

Experiments have been made on power required to crank motors at speeds from zero up. In one set of tests the cocks were left open, which is similar to the condition of an engine with a leaking, poor compression piston. In the other set of experiments the cocks were closed and compression was good.

At low speeds less power was required to crank the motor with cocks open, as would logically be supposed. But with increase in speed the difference in power requirements became less and less until the speed of 100 revolutions per minute was reached, at which point there was no difference at all. Above that speed considerably more power was required to crank the motor with cocks open. The effect of compression on a coasting motor car is therefore an open question and depends much upon the steepness and length of grade and other conditions as pointed out by the editor of this publication.

Power is always consumed in sucking air through a small aperture and forcing it out again. The greater the speed the greater the power consumption. Roughly, it varies as the square of the speed of the motor. By correctly fitting the cylinders with

Digitized by Google

pistons and rings and stopping these leaks, lost power on this account is eliminated.

I beg to call attention to the fact that I said: "I took particular pains to make everything as smooth-fitting and frictionless as possible." The only thing I did to the pistons and cylinders was to lubricate and clean them.

Chauffeurs' Cramp.

From H. G. Scott in the New York Sun.—I desire to obtain, from persons driving their own automobile, from chauffeurs and from members of the medical profession, representatives of accident insurance companies, or others, any and all information possible as to "chauffeurs' cramp" of the leg, thigh or back, induced by the relatively fixed position of the leg when driving.

Details, too, would be valuable of any actual accident where such cramp was known to have caused accident or was believed to have been a factor.

No data on this subject seem available, and as it appears to be of importance I venture to ask the aid of your valued columns in obtaining the desired information from your readers.

(Note by the Editor.—The foregoing is the first we have ever heard of "chauffeurs' cramp" and any reader who has experienced anything of the sort we shall be glad to hear from him with particulars.)

The Hickey Condenser.

In response to an inquiry in our June issue, a publication called "The Ford Family," states that the Hickey condenser is handled by a firm of that name, of 22 Battery Street, San Francisco, Cal. It is stated that this device prevents overheating of the motor and is easily attached to the radiator.

A Ford Car Trailer.

It is well known that the Ford car has power to propel more than the chassis can safely carry. For this reason and the fact that the Ford body has not sufficient room to carry bulky loads a trailer attached to the chassis has been used successfully, and the following illustrations will give an idea of its construction. In Fig. 1 is shown an express body, 9 feet 6 inches long. In Fig. 2 is shown a farmer's wagon, as a trailer on the Ford. The fifth wheel, which is located at the rear of the chassis, is shown clearly in Fig. 3 at A. It consists of a bed plate, B, to which is fastened two bearings, C. A shaft, D, is mounted in two bearings, E, and runs through the bearings, C. The bearings, E, are mounted on two T irons, F. The construction of this designed fifth wheel allows for a rocking motion, which is necessary, as there is a downward and upward motion on the rear springs of the wagon body or trailer. At G is shown the Ford chassis spring, and the chassis frame, H, to indicate the location re-

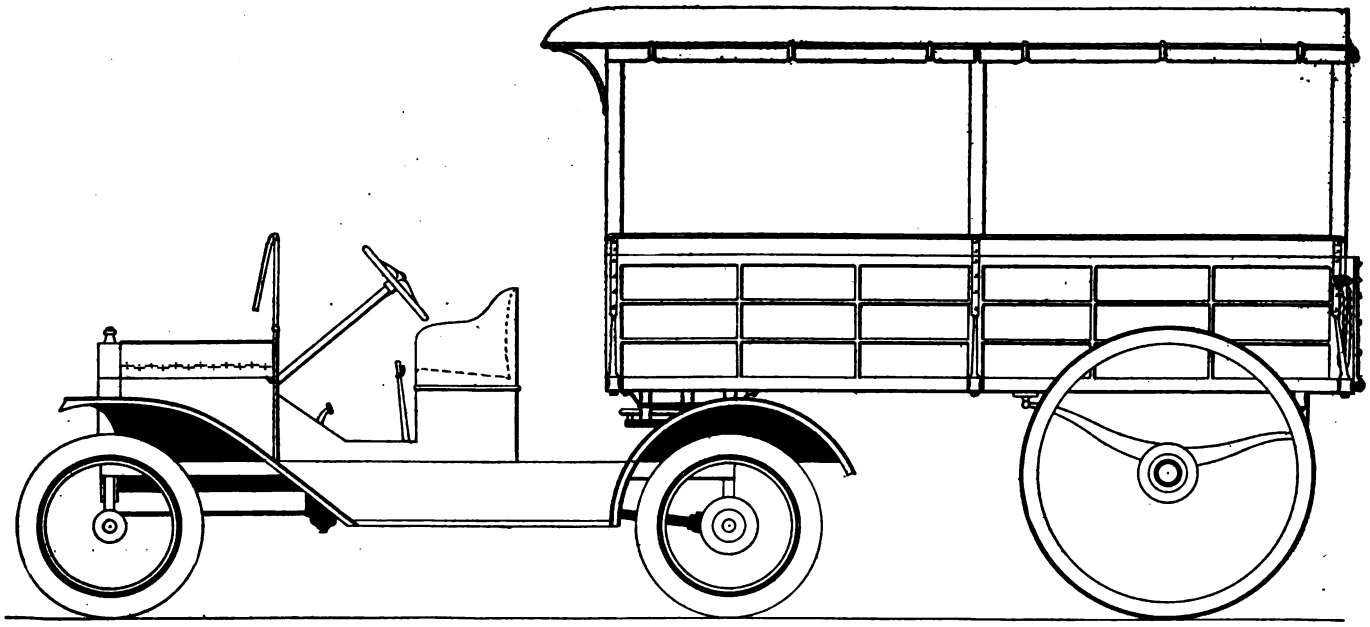

Fig. 1.

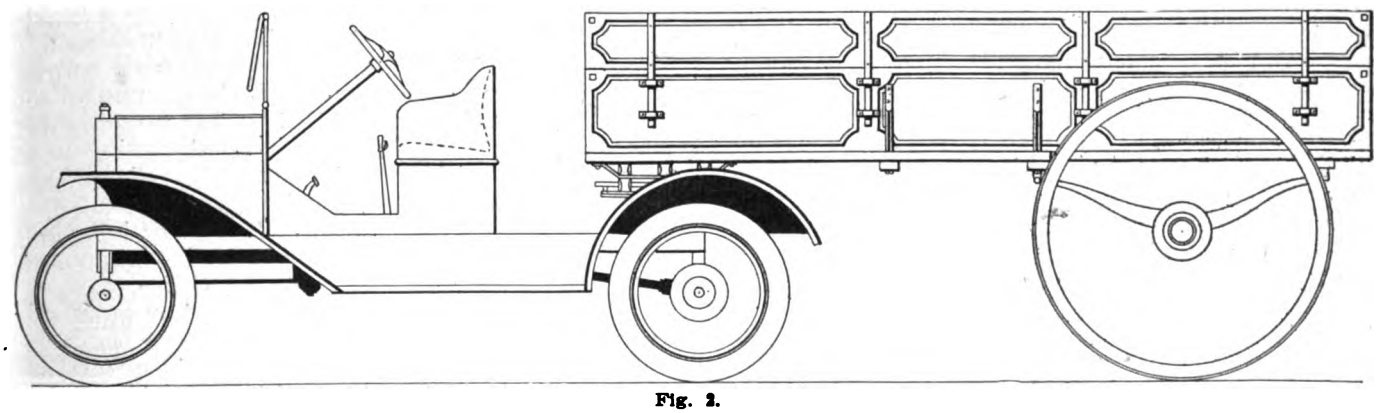

Fig. 2.

Digitized by Google

quired in this construction. The seat of the driver must be well forward to allow clearance in turning.

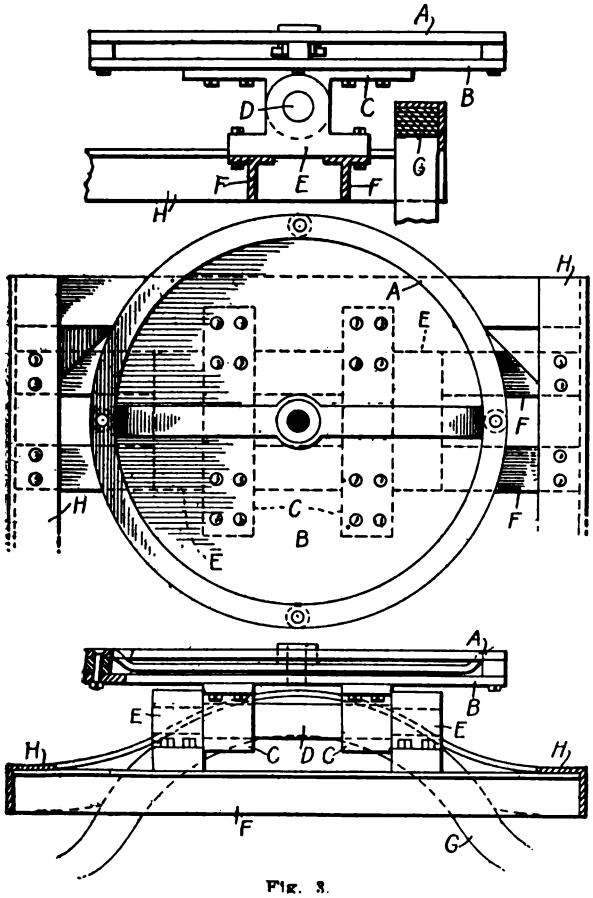

Fig. 3.

In the design shown the Ford chassis can turn at right angles to the body of the wagon.

THE FUTURE MAGNETO.

F. B. Williams Before the National Gas Engine Association.

Several years ago I was studying the engine catalogue of one of our progressive manufacturers. As usual I turned to the very last page to see what was stated thereon, regarding their magneto equipment. Here I found the following statement: "A magneto is a small electric generator that runs at a very high speed and generates enough current to fire the engine. Batteries are used for starting and after the engine is up to speed the switch is thrown over on the magneto. We recommend a magneto as it is a good thing and when it works it saves batteries. We can furnish this magneto for the small additional charge of twenty dollars." This was a step in the right direction, and the type of magneto referred to was superior to the hot-tube ignition, which is now obsolete.

In discussing the present-day magneto, of course, we will consider separately the make-and-break and the jump-spark. We will define the make-and-break as ignition in which the source of current is of such low voltage that the spark must be produced by a mechanical break of a closed circuit; this break taking place at the point where the spark is desired; that is, in the combustion chamber. We define the jump-spark as the development of a current of sufficiently high voltage to jump between two fixed points in the circuit known as the spark gap.

We will not enter into a lengthy discussion of the merits of the two systems. It is not worth while to try to make a Methodist out of a good Baptist, or to convert a good Baptist to the Methodist faith. Note that I have used the adjective "good" in both cases. If the best apparatus obtainable is used for either make-and-break or jump spark, results which are perfectly satisfactory can be obtained.

In analyzing the instrument necessary to produce an electric current, we must consider a few fundamental principles. A current can be produced by generation or by induction. An electric current is generated when a conductor revolves in a magnetic field in such a manner that its coils cross or cut the lines of magnetism. A current is induced when the magnetism of a core around which a conductor or coil of wire is wound is suddenly reversed, or when the core of a coil or armature is suddenly magnetized or de-magnetized.

A magnetic field can be produced by an electromagnet or it may exist in the form of a permanent magnet or magnets. It requires a certain amount of current to form an electro-magnetic field. In the old generator or dynamo form of instrument the current produced by the generator itself had to make its own magnetic field. This is the reason that a direct current "dynamo" magneto has to be driven at such a high speed before it generates enough current to fire an engine. It is like pumping water from the bottom of a deep well when the pump is "run down." You have to pump a long time before the water "comes."

In a modern magneto the magnetic field is in the form of permanent magnets, the use of which make it possible to produce a current at much lower speeds.

To produce a good current in a modern magneto, the parts are so arranged that the armature or the core of the coil has its magnetism reversed or suddenly raised or lowered by a change of its position relative to the magnetic lines which are produced by a field of permanent magnets. This is exactly what takes place when the armature of a magneto of the conventional form is turned one-half or even one-sixth of a turn.

In a direct current generator it is necessary to commutate the current. A considerable number of coils are revolved in the magnetic field, each coil is connected to a separate segment of the commutator. Two or more brushes are applied to the commutator in such a manner as to keep the current flowing in a constant direction; hence, the term "D. C."—direct current. This would appear to be a good feature as such a magneto does not need to be timed; but this advantage is more than offset by the inherent source of trouble in the commutator. Brushes stick or wear out and the commutator becomes coated or gummed up with a substance which shorts between the segments. This condition impairs the efficiency of the instrument. The necessity for high speed and the limited output at low speeds resulted in the introduction of governors, which are a source of trouble. The logical application of this governor was to use a friction drive against the flywheel. The unreliability of this entire system is now so well conceded that the use of the direct current friction drive magneto, except as a makeshift on old engines for which better provisions have never been made, has become almost a thing of the past.

The better and later practice in low tension design

Digitized by Google

is what is known as the alternating current magneto. Instead of using a number of coils and commutating the current, a single winding is used. In this there is generated or induced two distinct waves of current, one positive and one negative, during each revolution of the armature. These current impulses are very much stronger in proportion to the armature speed than the current produced by a direct-current magneto. Instead of commutating the current, a permanent contact is made between the armature winding and the fixed collector. The fact that the commutator is not required makes it a simple matter for the skillful designer to make a collector that is entirely free from trouble. There are thousands of these machines in service where the collector is so simple and efficient that it requires no more attention than an engine flywheel.

We stated that this type of magneto produces two impulses of current each revolution. This being the case, there are two positions of the armature in each revolution where there is no current. The cycle of current output of an alternating current magneto is so suddenly built up from a neutral point to the point of greatest current value and then to gradually die down to the zero point; this cycle being repeated every half turn of the armature.

If current was required during an entire revolution of the engine flywheel, this type of magneto could not be used. Fortunately, a spark is required at a certain point only; during each revolution of the engine on a two-cycle motor, and during every second revolution on a four-cycle motor. It is therefore simply necessary to so time the magneto armature that a current impulse is available whenever it is required. This is the reason for driving an alternating-current magneto in timed relation to the engine and it accounts for the familiar term "gear-driven" or "built-in" magneto.

The modern alternating-current "gear-driven" magneto for make-and-break, therefore, consists of the following parts: A substantial housing or structure which supports permanent magnets and carries end plates with supporting bearings for the armature. Permanent magnets properly fitted and secured to this structure. An armature that is mechanically substantial and so proportioned and constructed as to give the best results electrically. The armature winding and means of conducting the current from this winding to a fixed terminal. Marks exterior to the instrument whereby the position of the armature relative to the frame or magnetic field may be determined at a glance.

Simple as these details may seem, there is a great difference in the magnetos offered; each said to be the best that the market affords, and said to last as long as the engine. Some of these differences are apparent to the man of ordinary training, while others can only be determined by special tests.

Take the question of magnets. It is conceded to be possible to make a magnet that is absolutely permanent. It should be made of tungsten-alloy steel, properly proportioned. Its shape should conform to certain established laws; while the heat treatment of this steel is of the greatest importance of all. The first item depends on the skill and the reliability of the steel manufacturers, and the thoroughness with which he is checked by chemical analysis and inspection of the finished product. The proper form can be determined at a glance. The use of straight bars for magnets or U-shaped magnets having a width of span practically equal to their height should obviously be avoided. A magneto may show a high reading on an ammeter or voltmeter and a good spark at the "peak of the wave," but may lack in current range. Such a magneto may have to be timed so accurately that it will give good satisfaction in the hands of the user.

In selecting a magneto it is well to look at the general reputation of its manufacturers and the success that they have attained. In making tests, two important items are: successful operation at low speed and the range or the amount a magneto can be "out of time" without materially affecting its operation.

The perfection to which this type of magneto has been developed and its great popularity due to its perfect success, when used in connection with an igniter of proper design, is one of the striking improvements in stationary engine ignition during the past few years. There are manufacturers who use this type of magneto exclusively on engines of all sizes for starting as well as running. Many are also using, in competition with batteries, magnetos of this type on small engines where it was formerly considered necessary to use coils and batteries in order to keep down the cost.

We have just referred to igniter design, and it may be instructive at this time to mention briefly one important point in this connection. Too much emphasis cannot be placed on the need for thorough insulation of the stationary electrode of a make-and-break igniter. Careful tests have shown that the "kick," when a make-and-break circuit is broken, is about ten times the normal voltage. That is, a battery circuit of six volts will jump up to sixty volts, and a thirty-volt magneto circuit will jump up to three hundred volts. One of the worst failures that has been recorded in connection with alternating-current magneto ignition occurred where a firm attempted to use a high voltage magneto on a kerosene engine with a poorly insulated igniter. Some magnetos of this type were originally used to produce a current of 100 volts. This practice has been changed. The matter of determining the voltage is a compromise between a low voltage that is easy to insulate, but is hard on contact points and the high voltage winding which gives a better spark at extremely low speeds. Current practice is to wind a medium size magneto so that it develops about 30 volts, and some very large magnetos are wound to develop as high as 60 volts.

In designing an igniter, the problem, therefore, is to insulate against a pressure of from 300 to 600 volts. No matter how strong the current is at this source, the quality of the spark is determined by the amount of current in the circuit where it is broken at the contact points. A leakage at the igniter or a partial short may greatly lessen the efficiency of a spark even from a battery; and it is evident that a magneto requires the best of insulation.

There has been a tendency among engine manufacturers to improve their insulation and a considerable number of them have adopted the N. G. E. A. method. This insulation will withstand the current from a high-tension magneto, that is 20,000 to 30,000 volts, and the writer has never heard of insulation trouble where it is used. It is to be regretted that a large number of engine builders hold up their hands at the suggestion of a change of this

Digitized by Google

detail, disregard the advantages of standardization and refuse to make this improvement.

We will take up the subject of oscillators as used in connection with both make-and-break and jump spark.

There is nothing radical or new in this method of ignition. Oscillators have been used in Europe for a great many years. In high grade expensive units their history in this country dates back much farther than most people are aware of.

The principles involved are exactly the same, so far as the production of current is concerned, as those used in rotating magnetos; a change is the relative position of parts which causes a rise, a fall or a reversal of magnetism in an iron core around which is wound a coil of wire. Springs are employed in order to produce a quick throw of rotor or inductor. Energy is stored up by a gradual extension of the springs and the instrument is so designed that when the oscillator trips and the parts are thrown back to normal position, a sudden impulse of current is developed. The quick movement that is obtained by this method makes it possible to use an instrument that would be of no value when used as a rotating magneto except when driven at a very high rate of speed. In other words, the oscillator method of generating a current produces the necessary current value independent of the speed at which the motor is driven. It is in this respect that oscillators have a certain advantage on large engines.

I might state that the only excuse for the use of an oscillator is the fact that large engines can be started on them more readily than on a rotating machine unless special means are employed for tripping the igniter by a backward throw of the engine. The apparent advantage carries with it certain inherent weaknesses. The use of springs with the strain and jar which their action involves produces an element of wear much greater than a smooth rotating motion. This is particularly true when the entire strain of the springs is carried on the oscillator itself or is transmitted through the armature or rotor. It is only recently that a new application has been developed whereby the strain is carried on heavy arms and studs that are built onto the igniter. This new detail removes one of the most serious objections to an oscillator and is a long step towards its perfection.

Another feature I might mention in connection with an oscillator is the fact that its current wave is necessarily very sudden and of short duration. In order to utilize this current on a make-and-break igniter, the mechanical connection between the oscillator and the movable electrode must be direct and positive. In order to take care of wear on contact points, it is customary to make this connection adjustable. The current belief that it is easier to time an oscillator than a rotating magneto is a mistake. In fact, the opposite is true. The time element during which the current from an oscillator may be used is instantaneous and unless the contact points open at the same instant, you will not get a spark. This is especially true of that type of oscillator that produces a very short peaked wave. My previous remark regarding the advantage of a low tension magneto having a wide range is very applicable in this connection. A rotating magneto that has an efficient current through a wide range is a superior instrument when used as an oscillator.

The practice that is somewhat current at the present time of using an oscillator on very small high-speed engines, I believe to be a passing fad. There is a speed limit beyond which it is not practical to operate an oscillator. Again, what can be the excuse of using an oscillator on an engine so small that it can be started as easily on a rotating magneto as it can on a battery, when the rotating magneto costs less and is really more efficient than the oscillator usually recommended for this class of engine?

The high tension oscillator is a practical instrument, subject, of course, to the limitation above described. As the circuit breaker is built into, and is a part of the instrument, the matter of breaking the circuit at the proper time is more easily accomplished on a high-tension than on a make-and-break.

Summing up this phase of the magneto question: The oscillator has certain advantages in starting the larger engines. It also has disadvantages which recent developments have largely overcome. A successful oscillator and a well-designed plug entirely eliminate the use of a battery and is bound to grow in popularity. A magneto that is superior when gear-driven, makes a superior oscillator when properly mounted. There is no advantage or necessity of using an oscillator on a small high-speed engine. It is, of course, impossible to cover the entire field with an oscillator. On multi-cylinder work, it would be necessary to have an instrument for each cylinder. On heavy duty engines there is a growing tendency toward mechanical or air starters. These entirely do away with the need for the oscillator starting advantage. Two-cylinder tractors all carry rotating magnetos. For high efficiency, heavy duty work, the alternating current, gear-driven magneto has found a place that it will hold from sheer reliability and merit, even though a battery may be used for starting.

The principles involved in a high-tension or jump-spark magneto are the same as a low tension with the following additions: The primary current is stepped up or transformed into a current of a sufficient voltage to jump a spark gap. This is done by winding a secondary winding outside of the primary winding. A circuit breaker is inserted in the primary circuit and the sudden break in the primary circuit induces the high voltage current in the secondary.

The same relations exist between the high-tension and the low-tension magneto as exist between the jump-spark and the make-and-break coil. A high-tension magneto has the same parts corresponding each to each as a jump spark coil with the addition of the permanent magnets. In the high-tension magneto the instrument itself produces its own primary current and transforms it to the necessary voltage. If the magneto is designed for two or more cylinders, means are provided for distributing the high-tension current to the desired number of terminals. There is a so-called high-tension type of magneto that is simply a low tension with a circuit breaker and distributor, the transformer being a detached non-vibrating coil. These are less compact than the pure high-tension, sef-contained type. The pure high-tension magneto stands out prominently as the best ignition for high speed multi-cylinder work. Its success in the automobile field has established its popularity. This instrument in a certain conventional form, developed first in Europe and copied with minor modifications in this country, has for a good many years served well its purpose.

Digitized by Google

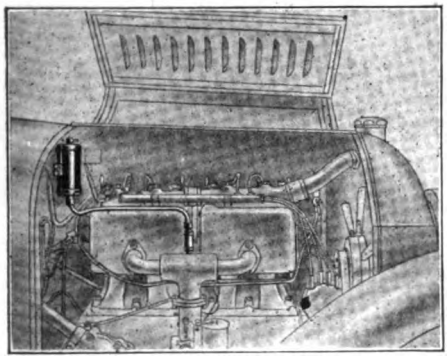
Oversize Tires.

From E. F. Smith, Chicago.—Some time ago Dr. W. B. Stine of Iowa, asked about the advisability of equipping his White Thirty with oversize tires. While the writer is at present using oversize tires, and intends to continue to do so, his story is far different from the one told by Dr. Stine, before he put on the oversize tires, 2,000 to 2,500 miles being the average mileage, against about 5,000 now. The three most important considerations are cost, mileage, and convenience, and from any one of these three angles I cannot see where the doctor would profit by equipping his car with oversize tires. 32x4 tires have sold for $22.75 each; 33x4½ for $32.00 each. Counting five tires as the proper equipment for a car, one would have to obtain 6,300 miles on the 33x4½ tires to equal the cost per mile of the 32x4 which are giving 4,500 mile average. With the ever present element of accidental injury, it doesn't stand to reason that a tire can be expected to give practically double the mileage on which adjustments are based by the manufacturers.

The matter of convenience is even more to be considered. In any locality where there are cars using 32x4 tires, and that means nearly any way station in the United States, one can buy 32x4 tires out of stock, without a moment's delay. Outside of the factory branches, there are over 100 tire dealers in Chicago who carry a stock at all times. Not one of the larger dealers at the time of writing could furnish five 33x4½ casings, and only six have any tires of this size on hand. If this is the condition in Chicago, what can be expected in smaller places?

The parties that are obtaining an 8,000-mile average on their tires probably have better road conditions to contend with than Dr. Stine, probably cover double the mileage per season, and incidentally may have tire equipment which has a larger margin of safety in the way of excess carrying capacity than his 32x4 tires afford.

The Oil Throwing Axle.



The following may be a cure: Take off the wheels; cut two washers, one for each wheel, out of thick felt, making them a fairly tight fit on the axle; push them close up to shoulder; replace wheel and screw up tightly. Use ordinary oil in the differential and this simple remedy completely cures the oil leakage. It is advisable to tighten the wheel again when the car has run, say, 300 miles. The washers will then be bedded in and should last up to 3,000 miles. As to the trouble entailed three-quarters of an hour is ample time for the complete job. This time he will save on the first occasion he washes his car.

NEW AND INTERESTING THINGS IN MOTORDOM

Starting and Lighting

Prevents Carbon and Saves Gas.

The Triplex Gas Economizer Co., 223 West 49th Street, New York City, has put on the market what has proven thus far to be a most simple and scientifically correct, fully automatic device, for removing carbon from motor cylinders, valves and plugs, and decreasing gasoline consumption. It consists of a brass tank carrying water, which is attached to the dashboard under the head and an automatic valve, set in the manifold above the carburetor where the gasoline vapor passes into the carburetor chambers, and flexible copper tubing connects the two. Its operation is ingenious, positive and effective. The tank construction is a copper tube covered with absorbent material passing down through the center with a water tight valve seat at its lower end. It is held closed by a spring at the top. There are two milled slots at the upper end of this tube, and four round holes in the top cover of the tank through which air is sucked over the water into the mixture at the manifold. This insures a constant supply of air of high humidity or moisture. It is mixed with the gas vapor in quantity proportioned to the speed and pull of the engine. To thoroughly clean the combustion chambers of carbon deposit, the engine is run at high speed until warmed up. By lifting the copper tube in the water tank by a lever in its upper end, and giving it a quarter turn, the valve at the bottom is opened and the water allowed to run to the warm combustion chambers where it is instantly converted into steam. The steam cuts and loosens the carbon which is discharged through the engine exhaust. At the end of this operation, which is not necessary except as carbon exists, the valve in the water tank is closed and the tank refilled. The manufacturers seem to be justified in claiming, after a year's test and operation of their device, that the constant mixture of moist air with the gasoline vapor thoroughly prevents the formation of carbon. No injurious chemicals are used. Moreover that the proportionately increased introduction, automatically accomplished, of air with the gas mixture, cuts down the gas consumption from 10 to 40 per cent. This, of course, increases the mileage per gallon of gasoline and is thus a saving in gasoline bills.

Triplex Gas Economizer.

Master Vibrator for Ford Cars.

Illustrated herewith is shown a master vibrator for Ford cars, made by the New York Coil Company. It will be seen that provision is made whereby the bracket may be shifted higher on the right hand side, which allows screws to find a solid foundation in a wooden sill provided under the upholstery. In this position the vibrator is readily accessible and does not take up any leg room in the car. Wires provided with connections are supplied, which enables the owner to make the proper connections to the magneto to secure the best results from both ignition and the lighting systems. All models put out are equipped with these additions so that they will fit either the old models or the new 1915 model, enabling the dealer to supply all models from one stock.

Master Vibrator for Ford Cars.

Digitized by Google

Master Spark Plugs.

The Master Spark Plugs made by the Hartford Machine Screw Co. of Hartford, Conn., are built on the principle of quality first. This year they are featuring their Ford Special, a new model, having carefully taken into consideration the peculiarities of the Ford engine. It is of unusual length—putting the spark way down into the explosion chamber—and should prove a favorite with Ford owners. In addition to this model there is the regular length Master which has

Ford Special.

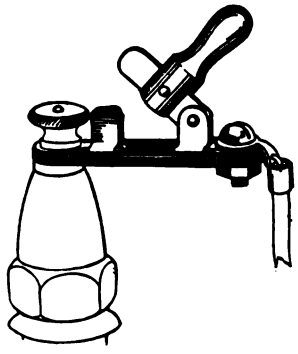
been on the market for somewhat over a year and is immensely popular, as well as the extra long—a plug designed for engines with extra thick water jackets, either automobile or marine.

It takes only a moment's observation to quickly note the finish, superior workmanship, quality of materials and a design which would serve to bear out the contention of the company manufacturing these plugs that they are absolutely leak proof, soot proof, and that the porcelain is as long lived as the steel shell.

Starting and Lighting Ford Cars.

That well known institution, the Westinghouse Electric & Mfg. Co., make an electrical equipment for starting, lighting and ignition for Ford cars that should appeal to all who want the best of service and the utmost reliability. Either the lighting and starting system, or the ignition system, or the lanterns will be sold separately if desired. The entire system consists of a motor-generator unit, battery and box, switches and everything necessary for installation. Dealers should address the Westinghouse Electric & Mfg. Co., Shadyside, Pittsburgh, Pa.

New Ford Timer.



The J. & B. Improved Ford Timer, made by the J. & B. Manufacturing Co., Pittsfield, Mass., is guaranteed for life. It is self lubricating, and automatically cleans the contacts, which insures electrical contacts at all times, eliminating the inconvenience of removing and cleaning the contacts which has always been the case where the trolley rotor principle is used. There is positively no wear to this Timer. There are no pivets, rollers, or moving parts. The rotor is one unit and self-contained. With this Timer you get a wipe contact instead of a rolling contact. The contact is made by a low resistance composition brush which makes a positive wipe contact. There is also a felt wiper which travels ahead of the current pick up brush which positively keeps contacts clean at all times. The price is $2.25.

Connecticut Ignition for Fords.

A. J. Pickard & Co. has been appointed exclusive distributor for a new ignition system for Ford cars which is being placed on the market by the Connecticut Telephone & Electric Co., Meriden, Conn. This is practically the standard Connecticut Automatic ignition system with the necessary brackets and wiring. The dashboard switch incorporates the usual automatic kick-off but has two buttons in place of the usual three where a magneto is used. The system is intended for use only on Ford cars which are equipped with a storage battery for lighting. A feature is that only the switch appears on the dash.

A New Spark Plug Switch.

William J. Bailey, of Newark, N. J., is placing on the market a spark plug switch, which is illustrated herewith. With its use no other tool is necessary

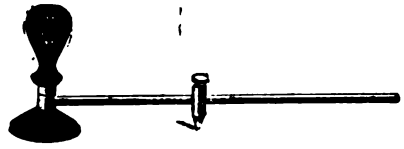
For Testing Spark Plugs.

for testing out spark plugs. One person alone can test any number of cylinders and there is not the slightest danger of an electric shock. It will fit any spark plug and is positive and accurate in its work. It is guaranteed and the price is but 25 cents.

A Reliable Spark Plug.

The National spark plug is the result of both experience, experiments and a combination of the best material for the purpose. It is easily cleaned and practically indestructible. The manufacturers, the National Spark Plug Co., Sedalia, Mo., are looking for dealers to sell this spark plug and offer a liberal discount.

The Lighting Problem Solved.



The Carleton generator which gives 7 volts, 49 c. p. direct current, means a steady light for automobiles with or without storage batteries. It has special brackets to attach to the Ford, Saxon and Metz cars, but is applicable to any car, motor cycle, boat or stationary plant. It is of high quality and the price is moderate. It is made by the Carleton Generator Company, 180 Summer Street, Boston.

A Fuel Saver and Lubricant.

The Chandler Sales Co., of Chicago, Ill., make a fuel saver and lubricator which increases the mileage in gasoline and gives a smoother and better running engine. It is a mechanical device and many who have used it have felt impelled to send to the manufacturers their high endorsement. It consists of a small valve arrangement to open into the intake manifold under the high suction existing at closed throttle and does not open on the extreme idle. Those interested should address the firm as above.

Cutting Your Headlights.

The man who has cars to repair can add to his profits if he will cut headlights himself. This has been made easy by special headlight circular glass cutters of the famous "Red Devil" make, as shown by the illustration. With its adjustable round steel rod and head, enam-

Red Devil Glass Cutter.

eled wooden base and handle, and a rubber mat on the base to prevent slipping, it will be found a handy tool, that pays for its entire cost practically every time it is used. It costs only 50 cents postpaid. "Red Devil" are the only glass cutters equipped with genuine hand honed steel wheels. The makers, Smith & Hemenway Co., 129 Chambers St. New York, think so much of the cutting quality of Red Devil Glass Cutters that each wheel for each cutter is individually selected and tested.

Diffuses the Automobile Light.

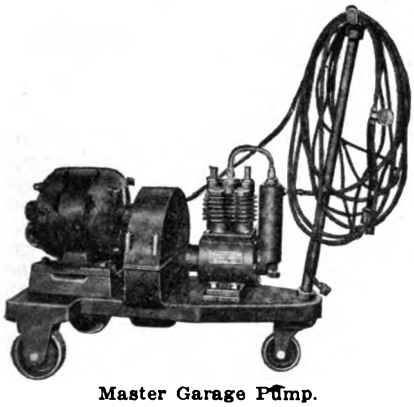
The use of a new device called Klearglow gives all the power of the lamps without the dangerous glare. It fits in any car and its merit has been proved in Europe where it was first invented. The firm manufacturing it has a business

No Dangerous Glare With This.

proposition for jobbers and dealers which they will be glad to give by addressing H. G. Paro, 743 Michigan Blvd. Bldg., Chicago, Ill.

Garage and Repair Shop

A New File.



The Grobet vibrator file is well nigh indispensable to the automobile user or repairman. It has a screwdriver end, is of the highest quality and will be sent postpaid on receipt of 15 cents, or with a liberal discount to dealers. The manufacturers are Montgomery & Co., Inc., 105 Fulton Street, New York.

Master Garage Pumps.

Particularly noticeable among the garage pumps on the market this season are the Master Garage Pumps, manufactured by the Hartford Machine Screw Company, of Hartford, Conn. They have added two new models to their already complete line—Models W and Y. A close

Digitized by Google

observation discloses a degree of workmanship and finish seldom attempted in the manufacture of machines of this kind, and selling at the low prices at which Master Garage Pumps are quoted. Model W is a two-cylinder pump which may be furnished either on a truck or stationary and is designed for use in the larger public garages where continuous demands are made for tire inflation and quick service must be delivered. It may be used either as a direct pump for supplying air directly into the tires or in connection with a compressed air tank installation in order to maintain a sup-

Master Garage Pump.

ply of air "on tap." This model is driven by a ½ h.p. General Electric Motor.

It is a large and powerful machine designed to stand the hard and abusive service to which a tire pumping machine is subjected in the large public garage and its simplicity and ease of operation make it exceptionally efficient and practically fool proof.

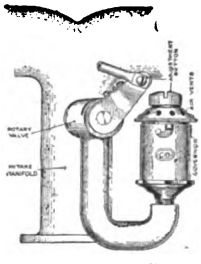
Model Y is a stationary belt-driven pump, built for garages which are equipped with a power unit and shafting. It eliminates the necessity of an extra motor and is a powerful pump, embodying the same sterling characteristics and quality as noted in Model W. The same general methods of construction and high quality of materials and workmanship obtain in every model. Each pump is fully equipped ready for use. The Hartford Machine Screw Company fully guarantee their pumps for one year and their success in marketing these pumps indicates that their quality is appreciated.

For the Motor

Light Pistons.

If you were going to try to most increase the speed and power of your car by reducing its weight somewhere, what would be the best place to do it? This question is easy enough to answer. It should be done by making the pistons lighter. With a given amount of reduction in weight, nothing would begin to so increase the power and speed of a car, and possibly it might not prove strictly accurate, but it would not be surprising if reducing the weight of the pistons one-half would increase the power of the motor very nearly that amount. These being the facts, the new Zephyr pistons ought to be unusually desirable. They are said to be half as light as the conventional type and this light weight is secured by having the material of the piston cut in and making it all hollow, except the head, while it is pierced with holes for further decreasing the weight. The manufacturers claim at least 25 per cent. more h.p. and less vibration of the engine, less tendency to overheat, reduced wear on bearings and less carbon and soot on the spark plugs. These are important considerations and although there is no space to go into the matter fully here, it may be stated that these pistons are being used widely abroad and will soon be in this country. For full information concerning these pistons for Ford or other cars, address the manufacturers, The Wridgway Co., Wilkes-Barre, Pa.

No More Piston Ring Leaks.



The Pressure Proof piston ring is sure to prevent leaking from any of the common causes, which are not only numerous, but oftentimes exasperating. It is self adjusting, does not wear loose, has an even tension and is guaranteed not to break. The spring expansion takes the strain and the cast iron rings do the packing. It means the highest efficiency on the part of the motor and is guaranteed by the manufacturers, the Pressure Proof Piston Ring Co., 3368 Washington St., Jamaica Plain, Boston, Mass. The company desires some responsible dealers and will be glad to send terms to them if they will write to the foregoing address.

A Guaranteed Carbon Remover.

The Hart-Bell carbon remover is made by the Utility Products Co., Times Building, New York. No chemical or acid is used, and it will remove carbon in less than 15 minutes. It conveys water from the outlet pipe to the inlet manifold and it is here converted into steam. This soaks into the carbon and gets under it, and it is thus worked out by the action of the engine. It not only removes carbon after it has been formed, but prevents it from being formed, and if found unsatisfactory the full purchase price will be refunded.

An Intake Valve Timer.

William J. Bailey, of Newark, N. J., is putting on the market an automatic intake valve governor and primer which will give more speed, a better mixture, and consequently more mileage to a gallon of gasoline. It is claimed likewise

Automatic Intake Governor.

that it reduces the carbonization, owing to the improved mixture, and that it gives more power for hill climbing. The cost is refunded if not found satisfactory. It can be used on all cars.

The Oscillating Valve Grinder.

Formerly, grinding of the valves necessitated having the car out of commission for a day, at least. As the expense was considerable and the inconvenience great, it was ordinarily neglected until the eleventh hour. The Oscillating Valve Grinder reduces the work to a minimum. Any novice can use it easily and quickly, with as satisfactory results as the experienced mechanic. It is a necessary adjunct to the well-equipped tool-kit; otherwise, the valves are almost certain not to be ground frequently enough to keep them gas-tight and the engine up to its highest efficiency. The accompanying illustration will give some idea of the

A New Valve Grinder.

simplicity of this valve grinder and how it is used. It is made by E. S. Michener, New Castle, Pa.

The Running Gear

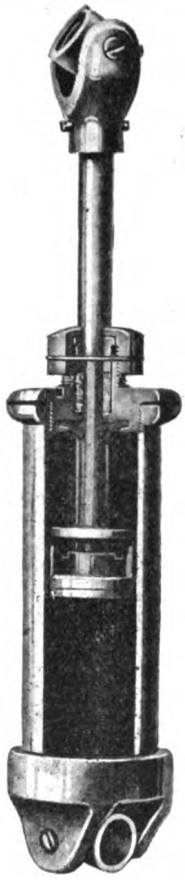
A New Tire Valve.

Most car drivers are aware of the fact that a common trouble of ordinary pneumatic tires is that air is likely to leak out of the valve. The Henemier valve is said to keep the air in all the time and the valve can be put in or taken out without any tools whatever. It is simple in construction, and the manufacturers have so much confidence in it that they offer to send to the trade a small valve so that they can test its advantages. These valves are packed, 100 in a box and retailed for 5c each. For full information address The Riess Manufacturing Co., 1688 Broadway, New York City.

A Motor-Bearing Reamer.

The Martell aligning reamer is made by the Harding Distributing Co., 40 Court Street, Boston, Mass. This device saves more than half the time of hand-scraping motor bearings and does the work perfectly. It was invented by an engineer who knew just what was wanted and found just what he desired. Two sets are made, one for ordinary motors and another for small motors. For further information write for a new book which the manufacturers will send free of cost, giving information as to how to scrape bearings better and quicker than ever before.

Pulls Both Wheels.



The M. & S. differential, which has recently been put on the market, insures a positive and equal pull on both wheels of the Ford car, and enables one to get out of any mud hole, or sand, or snow if one wheel has even the slightest traction. It likewise insures more mileage to the gallon of fuel and makes a better running car in every respect. The cost is only a trifle more than the regular Ford differential, and yet its advantages are

Digitized by Google

so obvious that details are hardly necessary. It takes but a few minutes to install it. The manufacturers, the M. & S. Gear Co., 1036 Whitney Building, Detroit, Mich., are making liberal offers of a sample for use on Ford cars. They are satisfied that this will be the means of selling a good many others.

A Hydraulic Shock Absorber.

The M. S. Company's hydraulic shock absorber is suitable for light as well as heavy cars, and is simple, safe and reliable. There are no springs, or anything else, to break or get out of order, and if a tire blows out when it is being used, the danger is eliminated almost entirely. It needs little attention, will out-last several cars and can be transferred from one car to another easily. With it you can make a better average speed and drive a car better than ever before. The firm make a model especially for Ford cars and when once installed it quickly proves its merit. It is manufactured by the Metal Stamping Co., Long Island City, N. Y.

Simple, Safe and Durable.

The "Ster-A-Ford."

The Ster-a-Ford safety steering device on your car means safety all the time. It gives absolutely perfect control at all times, doing so automatically, without effort or assistance from the driver. You can drive your car with a free and easy mind, no matter how rough and uneven or how sandy the road. If deflected by ruts, bumps or any obstructions, it will return instantly to its proper course with no attention whatever from the driver. It will save many times its cost each year in wear and tear on your car. Prevents all wobbling of front wheels and thus effects a big saving on tires and casings. Your car will last longer, ride easier, cost less for repairs and your mind will never be harrassed by fear of accidents. It is made by the Modern Specialty Co., Racine, Wis.

A Ford Car Safety Steersman.

The Badger Automatic Safety Steersman for Ford cars is an absolute insurance against accident and will keep the car running in an absolutely straight course no matter what the condition of the road. It also relieves the driver from the fatigue of steering. It is sold on a money back guarantee. The price is low and dealers are wanted. Address the Safety Appliance Co., Baraboo, Wis.

A New Tire Holder.

The Auto Parts Company, Providence, R. I., manufacturers of the well known Apco line of specialties for the Ford car, which are sold with the unqualified guarantee of "satisfaction or your money back," has perfected a tire holder for carrying the extra demountable rim, wire or spare wheel. The new design resembles the side tire holder brought out this spring in that it is attached to the running board, a location making for convenience as well as preventing the wheel or rim from being covered with mud, etc. The spare member is supported by two brackets secured to the running board, and the third bracket consists of an ingenious clasp that locks automatically. The clasp may be locked to prevent theft of the rim, and the lock is rubber covered to prevent rattling. One of the qualities emphasized of the new holder is that a rim or wheel can be removed or replaced in five seconds. The Apco holder can be fitted easily and quickly by the owner, comes complete with all necessary screws, etc., and is finished in black enamel. Thief proof qualities are obtained by the clasp covering the screws when closed. The new holder accurately fits the Ford size of rims and wheels and retails for $2.

The Purair Tire Pump.

This does the pumping while you smoke, or read, or enjoy yourself in any other way. It may be installed by any one. It is simple and durable and when it has the tires inflated to the entire pressure, it goes off with a loud noise so that no further time is lost. It does the work in a minute or two, and as it inflates the tires properly, it means more mileage, more wear for the tires and less danger of blow-outs. It is made ready to attach, with single cylinders, double cylinders and a Ford special, or the entire outfit will be supplied. It is made by the Hert Manufacturing Co., 150 South Delaware Street, Indianapolis, Ind.

A New Puncture-Proof Tire.

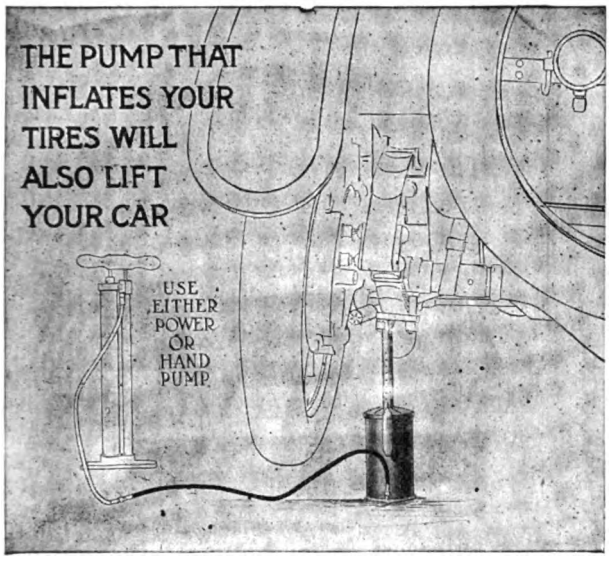
A new puncture-proof tire called the Woodworth Trouble-Proof Tire is now being put on the market by the Leather Tire Goods Company. The non-puncturable strip in this tire is made of chrome leather instead of metal or other stiff material. It has long been known that properly tanned leather is practically puncture-proof but the Leather Tire Goods Company has succeeded in incorporating the leather in the rubber tire, thus producing a puncture-proof tire that is resilient and non-heating. These tires are guaranteed against punctures for 5,000 miles and the manufacturers agree to pay the cost of repairing tires in case they are punctured. The tires are made of combed Sea Island Cotton and very carefully inspected in the manufacture to prevent any possibility of defects. It is claimed for these tires that under ordinary conditions, they will average much more than 5,000 miles and if used with good tubes the user will be free from tire troubles. A new booklet showing Woodworth Trouble-Proof Tires and a number of other devices valuable to motorists has just been published and can be obtained by writing the manufacturers, the Leather Tire Goods Company, Niagara Falls, N. Y.

A New Outer Tire.

A resilient outer surface for a tire is more valuable and makes the car run easier than the average automobile owner imagines. The O'Neil outer tires cover the whole outside of the old casings, making them look as well as new and insuring against creeping and slipping. Neither sand nor water can get beneath them. They give both a good appearance and long service and the price is low. They are manufactured by the O'Neil Tire & Protector Co., Akron, Ohio.

O'Neil Outer Tire.

A Ford Car Steering Device.



It is generally admitted that Ford cars, being light and having a short wheel base, are difficult to steer over rough roads. The Savidge steering device takes the wobble out of the front wheels, acting as a shock absorber on the steering, and very much increases the comfort and safety of riding. The manufacturers have an interesting proposition for dealers and as the price of this device is low it ought to sell rapidly. Address the Savidge Steering Device Co., 508 Murphy Bldg., Indianapolis, Ind.

More Floor Space.

Although the Kellogg Mfg. Co. of Rochester, N. Y., has been working night and day shifts the past three months, they have recently been compelled to make an addition of 15,000 square feet of floor space. This business, started seven years ago, has been steadily increasing. The entire plant and equipment is built around the demand for their engine-driven tire pumps, which the Kellogg Mfg. Co. has consistently and conservatively advertised. The increase of floor space from time to time, the introduction of special machinery and methods is an indication of the company's ability to take care of its customers. Plans are prepared for a larger plant and equipment, to be ready as needed.

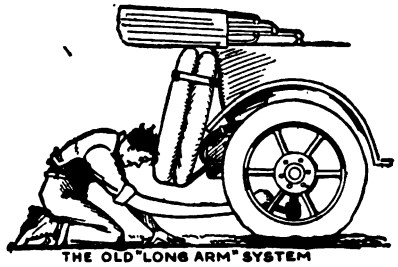
NATIONAL PNEUMATIC JACK

"JUST WHAT I HAVE BEEN LOOKING FOR"

—Is what people are writing us every day

HERE IS A JACK THAT WILL LIFT THE LARGEST CAR WITH NO WORK, NO DIRTY CLOTHES, NO "GETTING DOWN ON ALL FOURS" (like the man in illustration below).

THE "NATIONAL PNEUMATIC JACK" IS AS FAR AHEAD OF THE ORDINARY LEVER JACK AS THE SELF STARTER IS OF THE OLD CRANK.



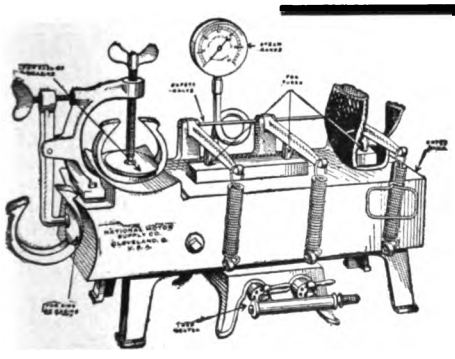
Just slip it under your car, attach either a hand or power pump to the end of hose, and up goes the heaviest car, AND STAYS THERE UNTIL THE AIR IS RELEASED. Has locking device for holding up car in storage. It can't slip. It won't sink in ground on account of its large base. You need not worry about long springs, rear tank, etc., being in the way. Five to ten strokes of ordinary hand pump will lift car. Order one for your old car, or specify that your new car be equipped with it.

Tell the agent he must furnish one with car—and he will.

Ten Days' Free Trial

Will ship one on trial, and if not satisfactory will refund your money. That's fair! Weight only seven pounds. Four inches in diameter, eleven inches high when closed, with six inch lift.

PRICE, by mail prepaid, $6.00



THE OLD "LONG ARM" SYSTEM
IS THIS THE WAY YOU WORK?

Garagemen

This is the jack for you. Just stick on air line hose, raising car instantly, with no slipping, skinned knuckles or hard work. Earns its cost in time saved. Nothing to wear out or get out of order.

Get the agency in your town.

GARAGE AND REPAIR MEN, LOOK!

Thousands of garage men all over the world are making big profits with the

NATIONAL GARAGE STEAM VULOANIZER

Vulcanizes three tubes and two casings at a time. Heated by either gas or gasoline. We have made this machine without any change for six years, which shows how satisfactory it is. You might as well have the big profits for vulcanizing in your vicinity. The National is the easiest and cheapest machine to operate on the market.

LIST PRICE, $60.00

Write for full details and discounts. A card will do.

New Era Shock Absorber.

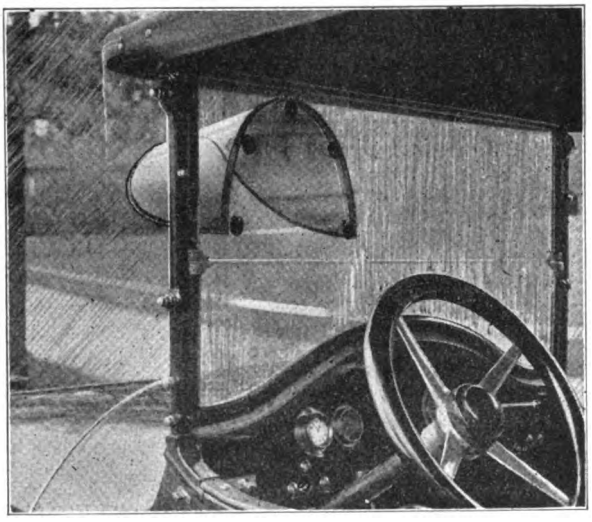
It should be understood, and probably is understood, tnat the New Era shock absorbers are made suitable for use on all kinds of automobiles, as well as for Ford cars. No matter whether the car is light, medium or heavy weight, they are sure to give satisfactory results. They have been before explained in these columns and it is unnecessary to refer to details. By the way, the New Era Spring and Specialty Co., with main sales office at 864-878 Woodward Avenue, Detroit, Mich., desires the trade to be advised that all mail and matters pertaining to New Era shock absorbers should now be addressed to the Detroit office, from which point all shipments of shock absorbers are being made, instead of from Hempstead, L. I., N. Y. Their arrangements for their manufacture at that point has been ordered forwarded on to the Detroit office.

A New Model Vulcanizer.

Lee C. Mapes, 16 Fulton avenue, Rochester, N. Y., has brought out a "Baby" Superior vulcanizer with a mould six inches long and six inches wide, which with complete equipment, is listed at $9.00. The base of this vulcanizer is 8¾ inches wide by 11 inches long and with stove, clamp and pressure brake weighs only 23 pounds.

Two-Speed Axles.

The two-speed rear axle used in the Cadillac 1914 model, is an infringement of the patents on this type of construction held by Walter S. Austin, of Grand Rapids, Mich., according to the decision of the United States Circuit Court of Appeals for the Sixth Circuit, sitting at Cincinnati, O. The decision of this court affirms the decree of the United States District Court for the Michigan district, handed down in favor of Austin in January of this year, and ordering an accounting and damages, estimated by Austin at $500,000.



Body and Top

Heat Proof Paint for Automobiles.

A new heat-proof paint has been placed on the market by E. R. Stowell, of Oden, Mich., and it is guaranteed that this paint will endure the heat and adhere to the exhaust manifolds, exhaust pipe and muffler on automobiles. This paint was first tested out for this purpose by William Remington, of the Stevens-Duryea Co., Chicopee Falls, Mass., and after a daily use of over six months was pronounced entirely satisfactory. It has been used on many other cars since and with perfect results. This paint is retailed at $1 per pint prepaid to automobile owners anywhere in the United States, and one pint is enough to paint the hot parts on any car. To dealers and repairmen a substantial discount is offered, and there is no doubt but that a good trade could be worked up in this article by many dealers. Inquiries should be addressed direct to the manufacturers.

A Real Rain Shield.

Herbert H. Frey, inventor of the spark-plug tire pump, Magneto type electric horn, and a number of successful automobile and other devices, has recently developed an accessory which is proving of pronounced interest to the automobile driver. Frey's U-Can-C Rain Shield is constructed of a flexible, transparent sheet of pyralin, easily arranged in any desired position like a visor or bonnet and held in operative position on the front face of wind shield by five vacuum cups. These cups hold with such force that the manufacturers guarantee that no wind can pull them off, although readily detached by pinching the thumb-nail under each cup. Water is prevented from entering the protected vision portion by a rubber sealing strip attached to the rear of the rain shield. The front edge of it is bound in such a way that water cannot drip off. It is manufactured by the Frey Manufacturing Company, 1514 Michigan Avenue, Chicago, Ill., and sells at $1.50 each.

Frey's U-Can-C Rain Shield.

The Jiffy Polishing Cloth.

This is a new article which has been placed upon the market by the Chemical Polishing Company. The manufacturers guarantee that this polishing cloth will make both the metal parts and the bodies of automobiles and motor boats shine so that they will actually dazzle the eye. Every housewife, jeweler and automobilist who has used the Jiffy polishing cloth, is ready to recommend it highly and good agents are wanted for this article throughout the country. The trial size of this cloth sells for only 10 cents. Inquiries should be addressed to the Chemical Polishing Co., sales room 426, 30 E. 42nd Street, New York.

Business Notes

For Maine Visitors.

The Maine Automobile Road Book for 1915 was issued this week and is now being sent out to members of the Maine Automobile Association and to tourists all over the United States. The new road book undoubtedly is one of the finest which has been issued by any State Association in the country. It contains 166 routes, covering every part of Maine and most of New Hampshire, much of eastern Massachusetts with the border routes in New Brunswick and the principal highway between the New England States and the city of Quebec. In addition the book contains the latest automobile laws of Maine, including those passed at the last session of the Legislature, which go into effect in July; the new fish and game laws of the State, the new forestry laws, rules for campers, a complete summary of notable facts about Maine, a list of the standard through routes of travel in the territory covered by the road book, including statements regarding some of the work which will be in progress during the summer, as well as the best ways to go from place to place; the new regulations for automobilists entering Canada, including the special war tax now in effect, the announcement of the opening of Mt. Desert Island to automobilists, and a scientific statement on the reason why the Maine coast is cool, a complete description of the points of interest along the routes contained in the book, as well as many other features. The book is being distributed through the Maine Automobile Association Touring Information Bureau, 12 Monument Square, Portland, Maine.

Dyke's 1915 Automobile Instructor.

A new edition, greatly enlarged, of Dyke's Automobile and Gasoline Engine Encyclopedia, has 640 pages, as against 596 formerly, and, in addition, a supplement of 32 pages devoted entirely to the Ford car. It contains 1750 illustrations and diagrams, as against 1,200 formerly. The subject of Electric Starting, Generating, and Lighting Systems is up-to-date in every respect. The subject begins with the elementary principles and step by step advances to the more complicated systems, as the Delco, Entz-Chalmers, Non-stallable, and other leading systems, which are all simplified. There are 67 pages and 142 illustrations on this subject alone. The ignition system deals with the first principles, and then advances to the modern systems, as Atwater-Kent, and other leading systems. Valve timing in degrees, ignition timing and repairing are simplified so a boy ten years old can understand. The author of the book is A. L. Dyke, of St. Louis, who has the distinction of being the originator of the first automobile supply business in America; publisher of the first practical books on automobiles, and manufacturer of the first float feed carburetor.

Mosler Spit Fire Plugs

Get this book now!

"Mosler on Spark Plugs" is the new Mosler guide which tells at a glance just which kind, type and size of plug is *right* for each engine. We are telling **Four Million** people a month to ask for a free copy at their dealer's. If you'll tell us how many copies you can use we'll send them to you prepaid. Your customers will be glad to get copies and you'll find it useful yourself.

And make sure you're stocked up with the full Mosler line, especially

Spit-Fire
Vesuvius
Superior

The line which is being advertised vigorously in the biggest national papers—The Saturday Evening Post, The Literary Digest, Collier's, Leslie's, The Scientific American, etc., etc. Always the best plugs to use, they're better than ever to sell. "If you don't supply your trade with Mosler Plugs, some other dealer does"—so runs the saying. Don't let him beat you to it—stock up now!

A. R. MOSLER & CO., **New York, N. Y.**

New Auto Supply Firm.

The W. E. Pruden Hardware Company of New York City is an example of a firm which after 40 years of business in other lines has, during the last decade, branched out successfully into automobile supplies. The fact that they also carry a large quantity of metals, general hardware and electrical supplies, all used at times in the automobile trade, has gained them the reputation that "If Pruden hasn't got it no one has it." Their policy has been to push the best quality of each line, along with high grade specialties of their own. Among the latter may be mentioned the Wepco Spark Plug, Pruden

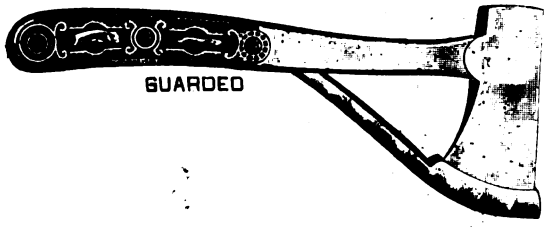
Wepco Spark Plug.

Valve Grinding Compound, Atlas Brake Lining and Wepco Brake Lining. Among their standard lines are Leak Proof Piston Rings, Sootless, Red Head, Champion, Benton, Rajah and Splitdorf Spark Plugs, Whitney Chains, Lunkenheimer Specialties, Starrett Tools, etc. Their catalogue of over two hundred and sixty pages is most comprehensive and is regarded as the reference book of the trade.

An Automobile Electric School.

The Arsenal School of Automobile Electricity, 401 25th Street, Rock Island, Ill., gives a six weeks' course of lectures and shop work that will enable a man to become an expert not only in starting systems and storage batteries but in all electrical work that a repairman is called upon to do. There is a great demand for experts in this field. Students are now being enrolled for the fall term.

The Most Car for the Money.



The above is what all car purchasers have the right to want, and they certainly seem to be getting it when they buy the Auburn car for 1916. Their four-cylinder car with ample room for five passengers, has all the improvements and accessories of the highest priced cars and the materials and construction are of the highest quality. The following are the specifications of this model which sells for $985: Four cylinders, T-head cast en bloc, 3⅞ x 5. Unit power plant. Three-point suspension. Cantilever springs. 114 inches wheel base, with standard 56-inch tread. Left side drive and center control. Electric lights and electric starter. Crown fenders, enclosed front and rear. Full U doors, with invisible hinges. New style electric head-lights, with small auxiliary lights, useful in city driving. Two-piece clear vision ventilating windshield. One-man top. 34 x 4 tires, demountable rims. Fully equipped without extra cost. Purchasers who have no money to spend for inordinate profits or slip-shod workmanship, and dealers who are looking for a car that "does its own talking," should address the manufacturers, the Auburn Automobile Company, Auburn, Ind.

The Harriman Engine.

It should fill every American with pride to know that a more dependable and efficient and really better engine is being built in this country today than in any other country on earth. And the factory where it is being made is in the little town of South Glastonbury, Conn. The 60 horse-power Harriman model weighs but 240 pounds, and it gives this power while running 1,350 revolutions per minute. These motors are four-cycle, water-cooled and have the valves situated in the waterjacketed head. The intake and exhaust valves are on opposite sides of the head and operated vertically. The valves are operated by an overhead cam shaft of nickel steel, which carries the water pump and magneto driving gear. Both intake and exhaust valves in each cylinder are operated by a single cam through the rocker arms. Cylinders are cast integrally with water-jacketed head. The barrel of each cylinder is machined inside and outside, insuring flawless metal and equal distribution of heat. The water jackets are of steel, welded to the grey iron cylinders by an autogenous weld. There is nothing freakish or untried about this motor. Those using it can be sure they are getting the most tried and approved construction and the best material. If any one is looking for a motor for an automobile or for a flying machine, and wishes to feel confident as to its unusual simplicity and permanent reliability and effectiveness he should address the Harriman Motors Co., South Glastonbury, Conn.

A Little Axe for Motorists.

The Marble Arms & Manufacturing Company of Gladstone, Michigan, is making a small axe which can be easily carried in the pocket and must be of great value to touring motorists. It is of course especially valuable where one

wishes to camp out and make a fire for tea or coffee. This little axe is provided with a shield which keeps the axe sharp and prevents the party carrying it from getting cut. Don't get it into your mind that this is anything like a big axe for chopping wood. The illustration herewith shows just how it looks. The manufacturers, during the quarter of a century or thereabouts that they have been in business, have established the reputation of making the very finest goods and this axe can be depended upon for doing the work required of it. Write for catalogue and price.—Advt.

Princess Motor's New Plant.

The Princess Motor Car Co., of Detroit, has leased the old plant of the Saxon Motor Co., at Bellevue Avenue and Frederick Street for a period of ten years at a yearly rental of about $39,000. The company makes a light car to sell at very low price.

New Tire Company.

The Monarch Stitched Tire Co., formed recently in Maine, has just purchased the Munroe-Eastman Co.'s plant at the border line between Newington and New Britain, Conn., in which the company will manufacture its product. The carcass of the tire is both stitched and cemented into the tread and a guarantee of 6,000 miles without the adjustment clause will be given by the makers.

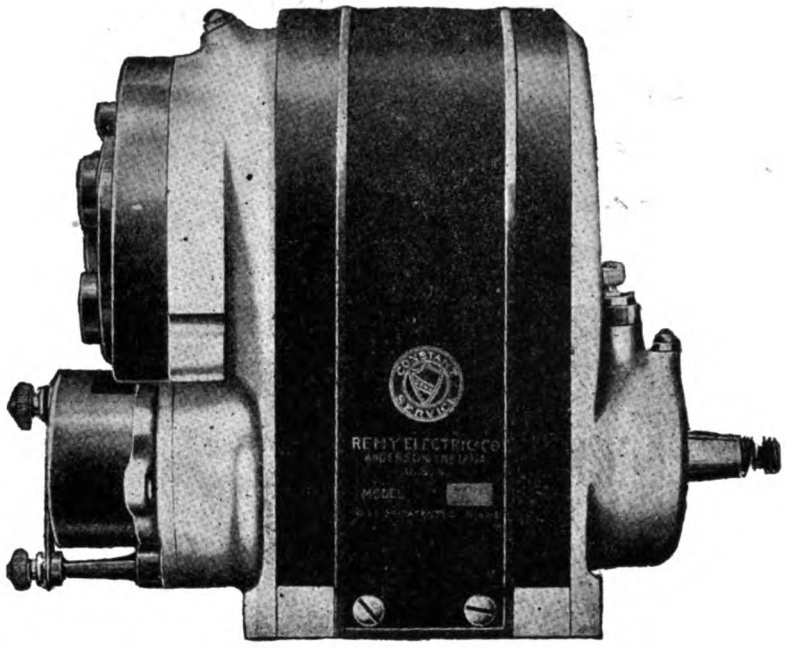
Ford to Make Tires.

The Ford Motor Co. will build its own tires in the new plant the company is to erect. An output of 2,000,000 tires the first year is anticipated, valued at $20,000,000. It is stated that the $5-a-day wage minimum will apply to all Ford workmen. It is also stated that the tractor will be sold with any style of wheel demanded by the soil to be worked.

New Branch Office.

The Ahlberg-Bearing Company have established a new branch office at 2831 Locust Street, St. Louis, Mo., which will take care of the Southwestern trade of this well known company.

Apco Price Reductions.



A reduction in the list price of two of its products is announced by the Auto Parts Company, Providence, R. I., makers of the Apco specialties for the Ford car. The valve stem adjusters now retail for 20 cents the set and the cut-out for 45 cents.

Touring Book Free.

Motorists contemplating a transcontinental trip the coming year to the Panama Pacific expositions in California can secure upon application to the Premier Motor Manufacturing Company, Indianapolis, a valuable book bearing on the subject. It is the record of the Premier owner's tour from the Atlantic to the Pacific. Besides giving one-day routes, the book tells the motorists what equipment should be carried and other valuable touring information. Frank E. Smith, head of the Premier, has ordered that the publication be distributed to all persons who expect to make an overland trip, upon their application direct to the Premier Motor Mfg. Co., Indianapolis.

PARKER-HYDRAULIC
PRESSED STEEL WHEELS For Ford Cars

STRONGER than WOOD or WIRE WHEELS

CHANGE TIRES and be running again IN TWO MINUTES

Forty pounds lighter per set than wood wheels with demountable rims
Carry your spare tire inflated on extra rim which we furnish

Note these facts: You get—

1. More mileage due to less weight and ability of steel to conduct heat from tires.
2. Quicker acceleration on account of the lighter unspring weight.
3. Greater mileage per gallon of gasoline.
4. Greater durability. Steel will not dry out like wood or break like wire.
5. Better appearance. Enamel is baked. It retains its lustre and does not crack off like paint.
6. Prompt service in mounting Parker-Hydraulic wheels. They can be put on at your garage in two hours.

OPERATION

To remove the rim: unscrew each bolt about three turns. The loosened clips may then be turned to release the rim. To put on new rim with tire: set rim on spokes having the upper position with valve stem between any two spokes and the rim will swing into position.

The Studebaker Line.

Greater standardization of the parts and further attention to production make it possible for the Studebaker Corp. to bring out its new models in large and more powerful form at reduced prices over those of the previous models. The price cut is more emphasized in the six, which is to sell at $1,050 as a seven-passenger touring model, and $1,000 as a roadster. For the previous seven-passenger six, the price was $1,450. In the seven-passenger touring model on the four-cylinder chassis, the cut has been $100, making it $885; while the new roadster is $135 less than previously, or $850.

The bodies are practically alike on the four and six chassis, and most of the difference in wheelbase is taken up by the engine. The cars are made to conform to the same general design throughout. In fact, they are much more similar this year than ever before, and practically the only difference in addition to the difference in number of cylinders, are the wheelbase, rear axle gear ratio, and rear spring size.

Novel Pump Connection.

Stevens & Co., 375 Broadway, New York City, have brought out an instantly attachable pump connection for owners and garages which does not require turning to apply and is secure from the possibility of slipping. This connection, which is listed at 35 cents, will secure a grip under almost any circumstances and will not blow off at high pressures. An air-tight joint at the valve is provided and the rubber valve seat insures long service.

Ford Postpones Payment of Dividend.

The $48,000,000 dividend of the Ford Motor Co., of Detroit, will probably not be paid for two years, as the difficulties in the Michigan corporation laws are complicating the proposed capital increase of the company from $2,000,000 to $100,000,000. It is the intention of the Ford company to advocate the passing of a law in the Legislature of Michigan, permitting the incorporation of the company with $100,000,000, a proceeding impossible at present because of the arbitrary limit of $25,000,000 placed on corporate stock by this State. Rather than incorporate under the laws of Delaware, Maine or Arizona, the Ford Motor Co. contemplates withholding the stock dividend until the necessary change in the law can be effected.

More Interesting Velie News.

With the announcement last week of the new Velie "Six" at $1,065, it was assumed that this car was to be the Company's entire offering for 1916, but such is not the case. The larger and well-known Velie "Biltwel" Six, Model 15, will be continued in both five and six-passenger models at a reduction of nearly $200 in price—namely, $1,400.

The model 15 has a wheel-base of 124", 34 x 4 tires, on the five-passenger size, and 35 x 4½ tires on the six-passenger. The latter model has disappearing seats, which entirely fold away into the back of the front seat. The motor is a Continental, 3½ x 5, with Gray & Davis starting and lighting systems and Atwater-Kent automatic ignition; multiple disc clutch, spiral bevel drive and every feature and appointment usually associated with a car of much higher price.

The quality and finish of the new models have not suffered in any way through this price reduction. Real leather and curled hair, the wonderful "mirror" body finish, careful fitting and workmanship, and thorough testing and inspection are all well-known Velie attributes which are looked for and are expected as a matter of course in Velie cars. The Velie Motor Vehicle Company at Moline, Ills., have planned a large increase in production, many new representatives have been secured and their well-known service plan is, therefore, brought even closer to the individual buyer. With the continuance of the larger car the buyer may secure a Velie in any size he prefers.

A Book for Ford Owners.

"The Ford Car" has recently been published by the well known firm of Norman W. Henley Co., 132 Nassau Street, New York, and the price is $1. Ford car owners should not be without it. It contains over 100 specially made diagrams and half tone ilustrations, two large folding plates, and in fact is by far the most complete and practical instruction book ever published on the Ford car. The book is easily understood and it is written by a man who has a practical as well as a theoretical knowledge of the subject. It is divided into five special chapters, grouping the various subjects in relation to the mechanism of the Ford car, including how to drive it, repair it, and care for it. The chapter on the repair and overhauling alone is worth many times the price of the book.

Ford Engine Chart.

This is for locating Ford engine troubles. It shows clear sectional views depicting all portions of the Ford power plant and auxiliary groups that are apt to give trouble, detailing all derangements that are liable to make an engine lose power, start hard or work irregularly. It can be carried in the tool box or pocket. It enables the owner or operator of a Ford car to locate derangements by systematic search, guided by easily recognized symptons instead of by guess work. It makes the average owner independent of the roadside repair shop when touring. Size, 25 x 38 inches. Printed on heavy bond paper. Price, 25 cents. Published by The Norman W. Henley Publishing Company, 132 Nassau Street, New York.

All Will Share the Patents.

Peace and co-operation in patent matters, rather than ruinous litigation, is being chosen by a preponderance of the members of the National Automobile Chamber of Commerce under a cross-licensing agreement that is calculated to be an example of importance to every large manufacturing industry. No less than 69 automobile companies, members of the N. A. C. C., have already entered the agreement, by which some three hundred patents, owned separately, will be thrown open to them all. It is expected that ultimately nearly all of the 93 companies having membership in the Chamber will come under the operation of the cross-licensing plan.

Tires

OWNERS

CUT YOUR TIRE BILLS

BY USING

Double Tread Tires

Send us your old tires and we will make from two old tires one double tread tire which we guarantee will give good service.

See that one has a good bead, the other a good tread. The cost will range from $1.50 to $3.50.

We pay express charges on receiving your old tires and return C. O. D. subject to inspection.

In case you have no old tires to send us we will sell you our own make double tread tires at the following prices:

Size	Plain	Non-skid	Size	Plain	Non-skid
28x3	$4.00	$4.50	36x4	$9.00	$10.00
30x3	4.50	5.00	32x4½	8.00	8.50
30x3½	5.50	6.00	34x4½	9.00	10.00
32x3½	6.50	7.00	35x4½	9.00	10.00
34x3½	7.00	8.00	36x4½	10.00	11.00
30x4b	7.00	7.50	37x4½	10.00	11.00
32x4	8.00	8.50	34x5	9.00	10.00
33x4	8.00	9.00	35x5	10.50	11.50
34x4	8.00	9.00	36x5	11.00	12.00
35x4	9.00	10.00	37x5	12.00	13.00

For all other sizes write for prices,

Be sure to state the bead, whether Q. D., Straight bead or Clincher.

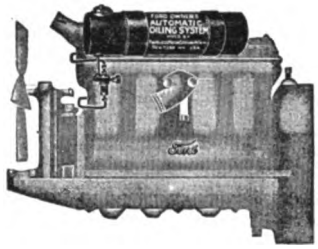
Lubricating Chart.

The Joseph Dixon Crucible Company, of Jersey City, N. J., is distributing among motorists, on request, lubricating charts that show where and how to lubricate a car. They suggest that owners and drivers hang this chart in their garage where they can easily get at it every time lubrication is necessary. The chart is very easily read. It shows a plan-view of a chassis with each part, where lubrication is necessary, marked with a number; and below the suggested lubricant is given opposite this number. The Dixon people are anxious to alleviate the lubrication troubles that most motorists have and have placed these charts in the hands of Dixon dealers for distribution.

The Modern Motor Car.



Among the numerous works of value in relation to the automobile, this book deserves a place in the up-to-date repair shop, and it might likewise be owned by every car owner. It not only makes the construction of the automobile easy to understand, but it gives a good deal about its care and repair. It is brought up to date with matter concerning electric lighting and starting and touches upon nearly all the new things that have appeared in the accessory line during the past year or two. It has 217 illustrations and contains 506 pages, which are clearly written and concise. It is divided into five sections. Section one relates to the construction of the parts of an automobile, together with their use and repair; section two is devoted to the material and supplies used in running a car; section three is devoted to electricity; section four to electric lighting and starting, and section five to ignition. The book is published by Laird & Lee, Chicago. Repairmen, owners, drivers, salesmen and students will find it both useful and instructive. The price is $2.50, and it is bound in flexible leather.

EXCLUSIVE SPECIALTIES FOR FORD CARS ☛ SUPERIOR TO ALL OTHERS

Absolutely Guaranteed

MONO-COIL DUPLEX VALVE ADJUSTERS

MONO COIL IGNITION SYSTEM. Gives freedom from all ignition troubles, operates on one unit, makes an old motor run as good as new, allows motor to throttle slower than when new without stalling, will prevent overheating due to faulty ignition, gives more power and speed on hills. This system is equal to a dual Magneto ignition system at a much lower cost. LIST PRICE, $12.00

AUTOMATIC OILING SYSTEM. Gives freedom from all lubricating troubles and eliminates the waste of oil and all the disagreeable work and attention now necessary. Starts and stops with the starting and stopping of the motor. (One gallon steel tank.) LIST PRICE, $8.50

DUPLEX SHOCK ABSORBERS. The only Shock Absorbers that take up the load from one to five passengers, can be used on two-passenger cars. The SIDE-LINKS are to prevent side rocking of the body. All shock absorbers raise the body not less than ¾ inch therefore shock absorbers without SIDE-LINKS throw enormous strain on the axle truss rods which are fastened to the motor base, and in due time will rack the motor to pieces as every time the car turns a corner the motor base receives the whole strain of the load. (Set of four) LIST PRICE, $10.00

VALVE ADJUSTERS AND SILENCERS. Gives freedom from noisy valves, increases power and makes the motor run smooth and quiet. (For eight valves), Set, LIST PRICE, $1.00

DEALERS, WRITE FOR OUR PROFOSITION

Manufactured by PEERLESS MOTOR SPECIALTY CO., Inc., 136-146 West 52nd St., New York, N. Y., U. S. A.

HOW TO BUY ADVERTISING

Buy it exactly as you would dry goods or groceries.

Be sure you get the quantity and quality you bargain for and at a fair market price.

To determine the good weight or measure, see that the publisher belongs to THE AUDIT BUREAU OF CIRCULATIONS. This ensures the quantity.

To determine the quality, find out who are the readers. If you want to reach automobile owners, garages or repairmen, do not advertise in mediums of general circulation, for this will be a shoddy quality—possibly 10 or 15 per cent. good. To be certain the medium is "all wool and a yard wide," choose one that reaches no other readers except those you want to reach; this means 100 per cent. good.

Finally, find out the market rates for advertising of the quality and quantity you are about to purchase—and pay no more.

If you purchase your advertising in this practical, business-like and fair way, you may be sure it will pay you, provided you have something to sell that those want to whom you appeal.

Maxwell Earnings $3,000,000.

The fiscal year of the Maxwell Motor Co., Detroit, Mich., will end July 31, and indications are that net profits will run close to $3,000,000 after liberal charges for depreciation, compared with $1,505,467 in the preceding year.

Patent Issued on Spring Leaf Spreaders.

The trade, and car owners as well will undoubtedly be interested in the fact that a United States Patent No. 1,142,280 has been issued to the Spring Leaf Lubricator Company of Ann Arbor, Mich. It is stated that this patent covers all spring spreaders with wedges no matter how operated. The patent is issued to Frederick Knowlson, manager of the Spring Leaf Lubricator Co., and we understand that it is the intention of this company to institute prosecution against several alleged infringers.

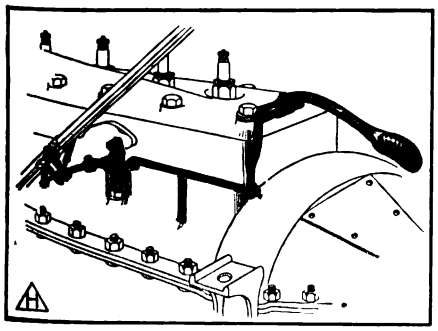
Attempt to Destroy Cars.

An attempt recently was made to burn a shipment of the motor cars destined for Russia while in the Northern Pacific yards at Tacoma, Wash., awaiting the vessel to carry them to Vladivostock. Oil soaked waste had been ignited under the boxes holding the machines. The guards have been doubled about the long lines of cars in the Tacoma yards.



New Ford Car Accessories.

Illustrated herewith will be seen two new accessories for Ford cars. The tire holder will fit tires up to 3½ inches in diameter. Holds one or two tires firmly.

Running Board Tire Holder.

Fastened to the running board by means of four bolts to each arm. The most notable feature of this tire holder is that it is supplied with a strong locking device, as shown in the cut. The foot accelerator is applied within 20 minutes

Foot Accelerator.

without boring holes or otherwise marring the car. Permits a perfect foot control, independent of steering wheel control. Both these specialties are manufactured by the Humboldt Machine & Stamping Company, 81-83-85 Tenth St., Long Island City, New York.

Diamond Tires.

John F. Lanier, in charge of the sale of Diamond tires in the Southwest, with headquarters at St. Louis, has severed his connection with The B. F. Goodrich Co., to accept a responsible position with the Norwalk Tire & Rubber Co., of Norwalk, Conn. Lanier is one of the "war horses" of the tire business. At various times he has been in charge of the sale of Diamond tires in Kansas City, St. Louis, Buffalo and New Jersey. In his new connection he will have entire charge of the sale of Norwalk tires for the central part of the country. Lanier says that he has seen a wonderful change in the tire industry in the many years that he has been selling tires.

Corbin-Brown Speedometer.

A red hand which indicates maximum speed and which cannot be set back to zero without the use of a special key has been added to the speedometer manufactured by the Corbin Screw Corp., New Britain, Conn. The hand, which by reason of its distinctive coloring, cannot be confused with the regular speed indicating hand, remains set at the maximum speed and the fact that it is locked there until released by the key makes it useful as a check on drivers of commercial cars.

Why An Eight?

In "Why An Eight?" the Cole Motor Car Co., Indianapolis, explains the reasons for its adoption of the eight-cylinder motor. It is a pocket-size booklet that tells clearly and in quite elementary and plain language the course of development of the eight. The advantages of the motor are fully given and the disadvantages not quite so much so.

Improved Body for Marmon.

The Nordyke and Marmon Co. has had a sample of its 1916 six on view at the factory during the last week. In specification, the new car is almost the same as the present type, but the body is a little wider and more care will be taken to insure the high class character of finish.

Garage $69.50

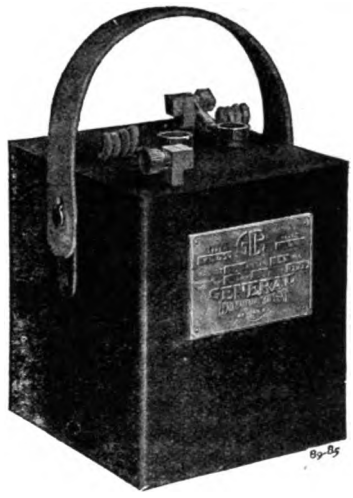
10x12 feet "Steelcote" Edwards ready-to-use garage. $69.50 complete. Factory price. Fireproof. Portable. Quickly set up. All styles and sizes of garages and portable buildings. Send postal for illustrated catalog.

THE EDWARDS MFG. CO.

423-473 Eggleston Ave., Cincinnati, O.

FORD OWNERS,

Here's a TIP for you.



The manufacturers of **Pres-To-Lite Ford Starter** will be ready to ship the 1916 improved model about July 15th. This model employs a compound geared lever, giving such power that a seven year old boy starts the motor with ease We advise Ford owners to write at once for particulars to

W. ROBERTSON, Greenwood Place, Buffalo, N. Y.

GLB Solve GLB Ignition Troubles

Dry Batteries are always a source of trouble. The expense of constant renewals at present prices (75% higher than usual) is extravagant when you can buy the **T. W. L.** Storage Battery, absolutely correct in quality, durability and capacity, for

$8.00 to $10.00 each

With a storage battery on your car you can also have a brilliant light at all times with minimum expense and trouble. The T. W. L. battery will last for years, as it is made up of thick separators and plates with a high ribbed jar.

Write for booklet No. 6.

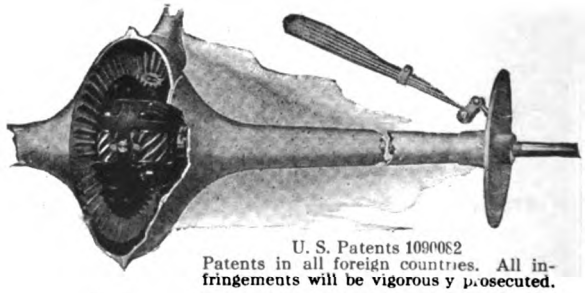
"Sure! I can put it in this afternoon—it only takes a few hours to install the

M. & S. Differentials"



That's the reason Ford dealers and accessory houses are flooding us with orders for the M. & S. Differential—Special Type for Ford cars—fits in the Ford housing, using the regular ring and pinion gears. Think of it! The M. & S. Spiral Gear Differential at only a trifle more than the ordinary Ford Bevel Gear Differential.

Every Ford owner is glad to make the change after he has once driven a Ford equipped with the M. & S. We can furnish special 3½% nickel steel Ring and Pinion Gears—4 to 1 ratio at $6.50 per set, if desired.

M&S DIFFERENTIAL

Special Type for Ford Cars

The M. & S. Differential is standard equipment on the Jeffery "Quad."

U. S. Patents 1090082
Patents in all foreign countries. All infringements will be vigorously prosecuted.

"Pulls Both Wheels"

Made for us by the Brown-Lipe-Chapin Co. of Syracuse—the largest makers of differentials in the world—from the same nickel steel and embodying the same principle used in M. & S. Differentials for the high-priced, high-powered cars.

The M. & S. Marks the Biggest Advance in Automobile Building Since the Electric Starter.

The M. & S. Differential insures a positive and equal pull on both wheels at all times. If one wheel has traction and the other does not, the wheel without traction can revolve no faster than the one with traction. In other words, the M. & S. is really an automatic differential lock which operates when a lock is necessary, yet differentiates wheel traveling in turning corners.

All the Power in the World Is No Good if You Have No Traction.

The M. & S. enables you to get out of any mud holes, sand or snow if one wheel has even the slightest traction. By insuring this positive and equal pull on both wheels, you save anywhere from 500 to 1000 miles' wear on the rear tires. You get more mileage to the gallon of fuel and you utilize all your engine power for work and not for idle spinning. The M. & S. transmits the power to the wheel or wheels having traction at **all** times, thereby minimizing the danger of **wheel skidding** and lessening the possibility of serious accidents, due to **loss of traction** by the rear wheels.

The M. & S. Is a Certain Moneymaker for Dealers.

Every Ford owner is a prospect. Every demonstration practically means a sale. You have no competition and it's so easy to sell M. & S. Differentials to Ford owners that you can make more money with less expense and effort than you can make selling cars. The cost is only a trifle more than the regular Ford Bevel Gear Differential, yet the advantages of the M. & S. are so obvious that no Ford owner will be satisfied with his present differential when once he has driven a Ford equipped with an M. & S.

To Ford Dealers--- We want every Ford Dealer to install an M. & S. Differential in a Ford Car and then drive it in sand and mud and over slippery pavements. To Ford Dealers we make a liberal offer on a sample Differential for your Ford.

To any one financially able to handle large territory in a big money-making way, we have an exclusive proposition. It will pay you to investigate.

M. & S. GEAR CO., 1036-1042 Whitney Building, Detroit, Michigan

The Most for the Money

Auburn Motor Cars for 1916 Announcement

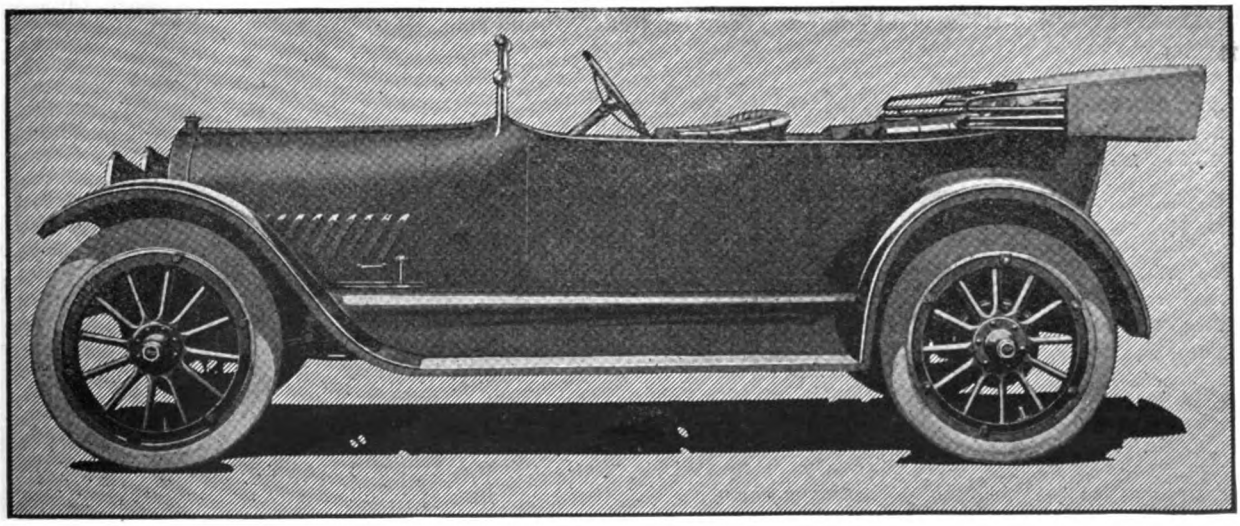
$985

Money Talks

Four cylinders, T-head cast en bloc. 3¾ x 5. Unit power plant. Three point suspension.
Cantilever springs.
114 inches wheel base, with standard 56 inch tread.
Left side drive and center control.
Electric lights and electric starter.
Crown fenders, enclosed front and rear.
Full U doors, with invisible hinges. Flush latches.
New style electric head-lights, with small auxiliary lights, useful in city driving.
Two piece clear vision ventilating windshield.
One man top. 34x4 tires, demountable rims.
Fully equipped without extra cost.

$985

The 1916 demand of the dealer and consumer are both met by this new Auburn—it makes money for the dealer, and gives the consumer more for his money.



The Auburn's performance is what makes its price low. It isn't a skimped car, but more actual service is added. The wonder is that the price has not been raised instead of lowered. Already this new car is a favorite in small towns as well as metropolitan cities. It is a credit to the Auburn's sixteen years of successful experience.

Six cylinders—3½x5.
A new and improved series of a successful and popular car.
Center control — left side drive.
Electric lights—electric starter.
Cantilever springs.
Roomy, comfortable and beautiful bodies.
Upholstery of selected stock.
One man top. 34x4 tires, demountable rims.
Crown fenders. Streamline bodies.
126 inches wheel base.
Spacious tonneau—folding and disappearing extra seats.
Ample room for seven passengers.
Full equipment without extra cost.

$1550

We have an attractive dealer's proposition for the right man, **no matter how small your home town.** It costs you nothing to find out.

10,000 MILES GUARANTEE BACKS THIS TIRE

TRY Brictson Pneumatic Tires at our expense. Don't pay until you are satisfied. At our risk find out for yourself what wonderful service Brictson Tires give—how resilient and easy riding they are. Get rid of punctures, blowouts and rim cuts. Brictson Tires are rut proof, oil proof and gasoline proof. They are sold under a specific 10,000 mile written service guarantee.

Read What One User Says

"Several months before beginning my trip from Detroit, Mich., to Detroit, Fla., I thoroughly investigated tires of several well advertised kinds. I finally decided for my trip that the Brictson was the most economical and durable tire that I could find.

I am daily asked if I have many punctures. I reply that I do not know what a puncture is. I am driving on all kinds of roads under all kinds of conditions and never have a thing to worry about.

I have been on the road since the 8th day of last October, and if all goes well will begin my Florida trip again about October 1st next. I consider the tires worth almost their weight in gold. I would not do without them at twice the price.

W. J. BREWSTER,
236 Jefferson Avenue, Detroit, Mich."

August 10, 1914.

Your Tires Rebuilt the Brictson Way

If the fabric in the tires you are now using is in good condition, we can take them, make them proof against rim-cutting, punctures, blowouts, side-wall breaks, skidding, ruts, oil, and give thousands of miles of additional service.

Sign and send back coupon for full information and details of our liberal Free Trial Plan.

STANDARD Hartford EQUIPMENT } FOR Ford CARS

A Perfect Ford Shock-Absorption Equipment

The Hartford Comfort Combination for Ford cars—

On Front On Rear

On the front of a Ford ***Hartford SHOCK ABSORBER**

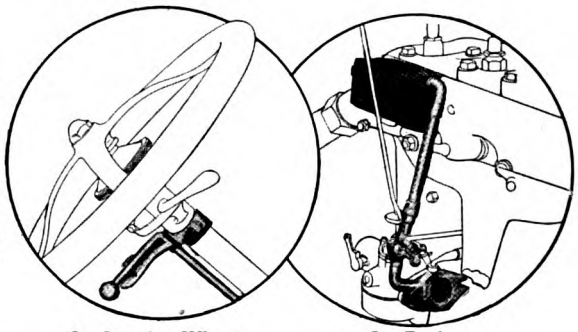
Hartford CUSHION SPRING On the rear of a Ford

The weight of the engine at the front of a Ford contributes to excessive spring action, here, when the road is rough. The Hartford Shock Absorber modifies or softens this action and eases the front of the Ford comfortably over bumps and ruts.

With less weight at the rear, the springs of a Ford, inclined to ride stiff and hard at this point, are given the needed resiliency to carry their load buoyantly and gently.

PRICE One Hartford Shock Absorber, Two Hartford Cushion Springs, **Fittings Complete, $12**

Ford "Gas" Bills Clipped One-Third



Those who are using the

Hartford Economizer

on their Ford cars say that it is **the most important Ford Accessory produced in a decade.** How true this is you will appreciate when you realize that it actually effects a saving of 15% in gasoline. More, it gives added power to a Ford engine and makes it run smoother.

By warming the air in its air stove, which gets its heat from the exhaust manifold, it feeds the engine **more** air and **less** gas. In fact, it produces **the** ideal mixture for a Ford engine. Figure a third off gasoline bill nd the Hartford Economizer looms as a mighty attractive buy at

Price Complete, $6.00

On Steering Wheel On Engine

Hartford Bumper

Insurance That Protects

When a ***Hartford Bumper***

is attached to a Ford car it improves its looks perceptibly. Gives the effect of a longer frame, of longer lines. When collision comes, no harm can come with it to lamps, mudguards or radiator. Two spring-steel, frictionally-absorbing arms rob every blow of the power to hurt foreparts of car and car itself. Bolts on without drilling.

Price, Complete, $10.00

Carburetor

5 Extra Horsepower

The *Brad-Kent* will add 5 horsepower to the working power of your car. It will carry you up hills and through deep roads that you cannot make at the present time. It will start the car more quickly and get you out of many a tight place. No matter what your present carburetor, we guarantee to beat it by at least 5 working horsepower.

10 Miles More Speed

No carburetor made can equal the *Brad-Kent* in quick get-away and average speed. We agree to give you at least 10 miles more speed than you now have. And you can secure this extra speed—when you want it—on even less gasoline consumption than now.

Saves 2 Gallons Out of 5

The *Brad-Kent* Carburetor gives a better and more uniform mixture than others. Both air and gas are automatically regulated by the motor speed. Just one adjustment and one moving part aside from float. Lighter, simpler and easier of regulation than other good carburetors.

Replace your carburetor with a *Brad-Kent* and we guarantee to save you 2 gallons of gasoline out of every 5 gallons you now have to use.

In a recent official test conducted by Mr. F. E. Edwards, Official Observer for the Chicago Automobile Club—a Model "T" Ford Touring Car was driven at an average of *33.12 miles per gallon.* This record was made in a run of 102.01 miles between Chicago and Milwaukee on country roads.

Can you get this mileage with your present carburetor? Then why not try a *Brad-Kent* for 30 days and see what it will do for you?

Shipped on 30 Days Free Trial

The complete Ford outfit includes a *Brad-Kent* Carburetor, manifold, hot air tube and stove. It fits any Model "T" Ford car and can be easily installed. Try it at our risk. $15 at your dealer or direct if no dealer near you. We positively guarantee the extra power, the extra speed and the gasoline saving claimed in this advertisement. Mail the order blank and make us prove it to you.

Dealers: Write today for our attractive dealer proposition. The *Brad-Kent* sells to every Ford owner who tries it. We will help you sell them in your territory. Write for full particulars.

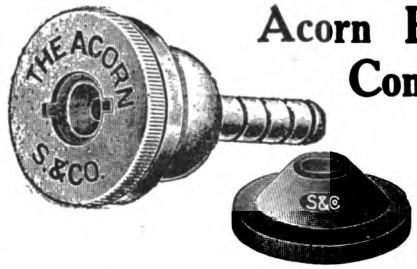
Boxed Assortments

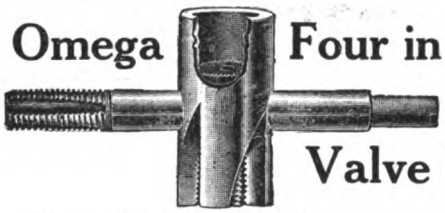


Standard Quality Full Count

A great convenience for the car owner. Special Large Assortments for the dealer.

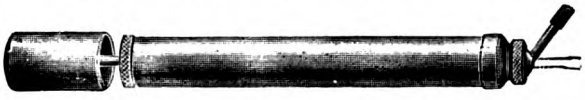
Cotters	Machine Screws
Lock Washers	Wood Screws
Bolts and Nuts	Taper Pins, Etc.

Acorn Pump Connection



The original and most satisfactory Pump Connection. Can be used on any Valve Stem or Pump.

PRICE 25c EACH



ACORN RED HARD RUBBERS will fit any connection of the Acorn Type. The tough red rubber core gives lasting qualities, five to ten times as great as regular gray rubbers. **PRICE 25c PER DOZEN.**

Omega Four in One Valve Tool

Re-cuts injured thread on inside or outside of stem. Removes Valves and re-faces top of Valve Stem. Carefully machined and finished. **PRICE 25c EACH.**

Pioneer Grease Gun

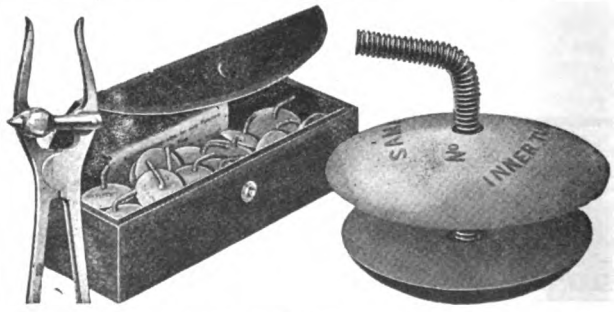
A substantially made Gun that will handle the lightest oil or heaviest grease with equal satisfaction. Furnished with large and small nozzle; nickel plated finish. **PRICE $1.50 EACH.**

Send for catalogue showing our complete line of automobile parts and accessories.

STEVENS
Automobile *Supplies Tools–Parts*

Dealers, Car Owners: Remember that all Stevens goods are fully guaranteed. Stevens goods must make good or we will. We go the limit because we know the kind of Quality, Material and Workmanship that go into Stevens products. It pays to get the name "Stevens" on whatever you buy.

SAMPSON FEATHEREDGE INNERTUBE PLUG



Punctures and small blow-outs repaired forever in 1½ minutes.

Here's a **permanent** repair for all punctures and small blow-outs. No cement. No vulcanizing. No patches. No disappointment. Anyone can do it—in 90 seconds. Autoists are wildly enthusiastic about it. Simple as A, B, C. With cutting edge of tool make clean, round hole. Spread hole with plier ends. Screw down plug. Snap off end of bolt. It cannot injure tube or shoe because of the pliant edge of pure, soft rubber. And the tube will never again leak at that point.

Guarantee: Sampson Plugs are guaranteed never to leak or injure tube or shoe. Money back at any time if you want it.

3 OUTFITS:

No. 1.	Tool and 6 Plugs in carton	$1.50
No. 2.	Tool and 12 Plugs in black enamel box	2.50
No. 3.	Motorcycle Kit, Tool and 6 Plugs in stout wallet	1.50

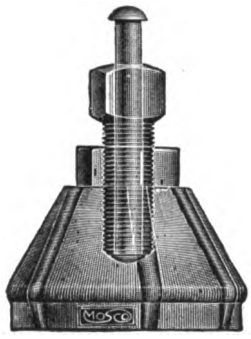
SPECIALTIES

TIMER SHAFT EXTENSION

Bemus Timer Patents { Sept. 24, 1907 / Dec. 17, 1907 / Feb. 16, 1915 / Apr. 27, 1915 } Others Pending

A New Timer for Ford Cars

The first Bemus Timers made in 1906 sold for $16.00 each, and they were worth the money. This **New Ford Model** sells for **$2.25** and is worth $16.00.



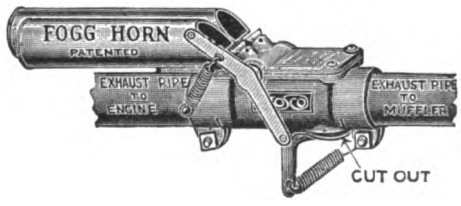
BEMUS BALL CONTACT TIMER *Costs More Worth More*

STOPS THAT SKIP. By reason of the method of mounting—on the time shaft—the main cause of skipping is eliminated. You will be surprised at the improvement here.

SMOOTHES OUT THE RUNNING to a degree which you would have believed impossible.

GIVES THE MOTOR MORE POWER, MORE SNAP, STEADIER PULLING, AND DOES AWAY WITH THAT JERKY RUNNING ON LOW THROTTLE.

PRICE $2.25



Patented { Mar. 24, 1914 / Dec. 15, 1914 }

WHEEL PULLERS

(Loose Plunger Type)

For Ford, Overland, Buick and Maxwell Cars

Every practical man knows that the only way to start a wheel which is "frozen" to the axle is to drive back the axle while pulling the wheel. Two men are required by the old method—the ordinary wheel-puller will never take off a stuck wheel—one man can do it easily with the MOSCO pullers. They have loose plungers extending through the screws—and bearing on the end of the axle. A blow with the hammer on the plunger, a turn of the screw, another drive with the hammer, and the wheel is off—no matter how long it has been on, nor how fast it is stuck. Information and prices on request.

FOGG HORN

for FORD *and* METZ Cars

Still going. Still blowing its clear, mellow signal on thousands of cars throughout the land. Some of the skeptics tell us that the electric horn has supplanted exhaust whistles, but we notice that the old reliable FOGG continues to sell. The reason? Because it is the horn located between the engine and the muffler, where it gets the full blast of the gas. Also because it has a cut-out in the body so that in buying the FOGG you get two devices in one—a signal and a cut-out.

PRICE, WITH CUT-OUT, - $5.00 **WITHOUT CUT-OUT, $4.50**

Make ONE Dollar Of Spark Plug Investment Do The Work Of THREE

Instead of keeping a stock of plugs with terminals to fit the three types of cable terminals installed on new cars at the factory, why not stock the plug that fits *all* terminals—JUMBO JIANT?

You cut two-thirds off the investment tied up in your stock of plugs—

Yet with a two-thirds smaller stock you can always meet the demands of the fellow who wants a plug in a hurry—whether he has plain, Q-D, or clip terminals. And you're protecting your customers' interests, too: because

JUMBO SPARK PLUGS

Are GUARANTEED For One Year

If any Jumbo Jiant shows any defect, the owner has only to return it to us with the guarantee coupon, and he gets a new plug without question or argument—this promise holds for 365 days after purchase.

Selling Jumbo Jiant plugs is one of the good ways of getting "solid" with your customers, because Jumbo Jiant is

NON-FOULING

—look at the electrodes, and you'll see why. No matter how much oil is splashed up against the plug, it drains away down the inclined electrodes, leaving the actual sparking point free and clear. If Jumbo Jiant ever stops sparking, it won't be soot that does it.

The way to begin is to begin—better write to-day for detailed information and prices.

UTILITY

PRICE $10.00
Complete with
Pneu-Meter

THE ONLY TRULY AUTOMATIC TIRE PUMP ON THE MARKET

The Pneu-Meter installed on the hose line prevents over inflation as well as under inflation. Connect your pump, set your Pneu-Meter at the right pressure, start your engine and forget it.

You don't have to watch your pump—the Pneu-Meter does it for you—when your tire is properly inflated, it becomes a **Safety** blow-off valve, using excess pressure to sound a continuous signal. **So simple a woman can work it.**

PRICE $2.00

UTILITY Jr.

PRICE $6.00
Complete with
Pneu-Meter

WHISTLING PNEU-METER

Sold separately and can be installed on the hose line of any other spark plug or gear driven pumps, garage air tanks, etc.

Absolutely accurate and cannot get out of order. Whistles loudly and can be heard fully a block away, and will continue until the engine stops.

Over and under inflation decreases the life of your tires. This is due to the use of tire pumps which are equipped with ordinary dial gauges and which at the best are inaccurate. This trouble and expense can be absolutely avoided by using **Utility Pumps equipped with Whistling Pneu-Meters.**

Smallest and fastest—simplest and best constructed pumps ever made—**absolutely safe.**

Built of rust-proof bronze, brass and nickeled steel. **LASTS A LIFETIME.**

7', 6' and 5' Long Respectively

The UTILITY Socket Wrench Set

A New Principle With Many Advantages

Has all the advantages of socket wrench sets consisting of fourteen wrenches, with none of their faults. Instant in adjustment. No screws to manipulate, or parts to get out of order. Can be applied to all shapes and kinds of nuts, immediately. Has many new features possessed by no other wrench.

SOME NEW FEATURES

Will grasp any nut instantly and requires no further effort to hold wrench in place.

In removing, the jaws hold nut firmly at all times, so it cannot fall or become lost. On the other hand, nut can be placed in jaws and applied to bolt or screw when same is inaccessible to the hands.

Unequalled for use in Garages and Machine Shops, in fact, wherever nuts and bolts are used.

Will take all nuts from ⅛ to ½ inch, inclusive.

Will take all nuts used in auto work.

Will take hexagon nuts, square nuts, wing nuts, cock nuts, and nuts rounded or distorted by use of other wrenches.

Cannot slip and bruise fingers of workmen, as jaws have rigid bearing on four sides—the harder you pull, the harder the jaws grab the nut.

Look at its wonderful advantages and then look at the price.

Utility Wrench Set Complete, $2.50

Packed in neat canvas bag.

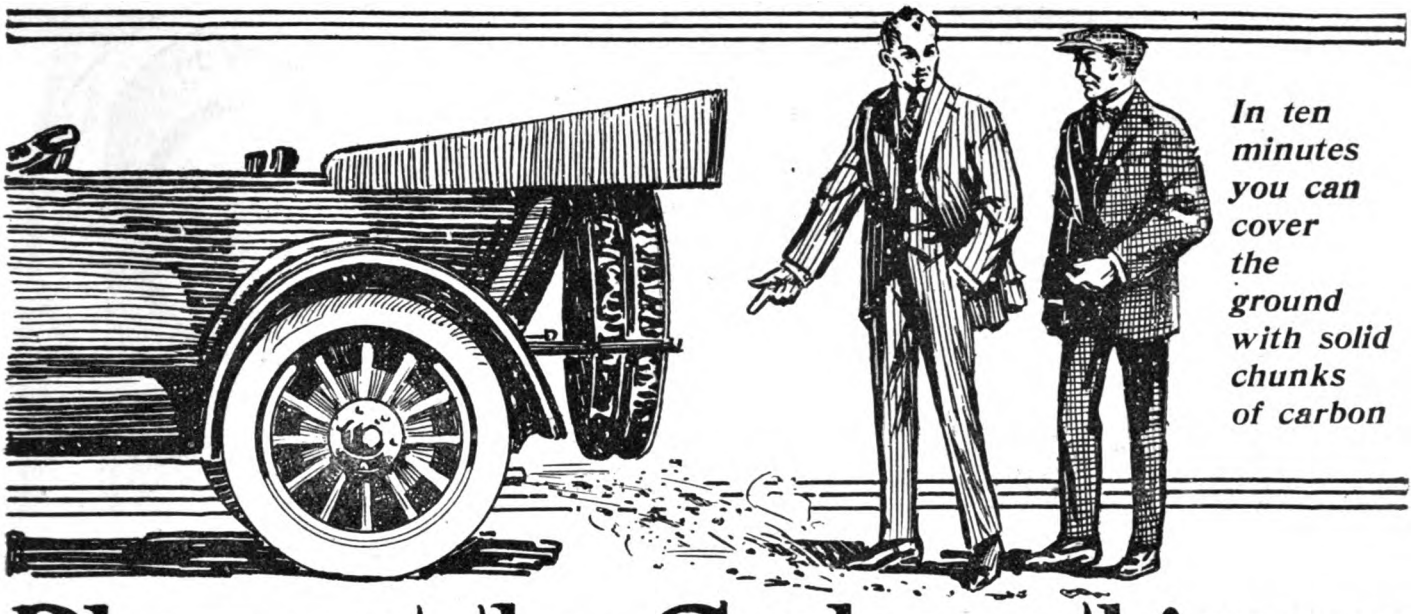
Write for Our Dealers' Proposition.

THE UTILITY DEMOUNTABLE RIM WRENCH

A Whole Tool Kit In One.

A Socket Wrench Set in itself.

Takes not only all sizes of nuts used in connection with demountable rims, but many other kinds and sizes.



Wrench can be folded when not in use.

Price $1.50

Blow out the Carbon this way

OF all the agencies in the world for attacking and softening hardened carbon, including kerosene, alcohol and other oils, **live steam** has been found to be the greatest of all.

The Hart-Bell Carbon Remover is a simple little device which you can attach to your car in a few minutes and is so constructed that wherever you may be when starting your engine, at the garage or while it is standing idling at the curb somewhere, you may in 5 or 10 minutes make the insides of your cylinders as clean as the palm of your hand.

CARBON HART-BELL REMOVER

The Hart-Bell Carbon Remover has no mysterious or alleged influence. It is not one of those chemicals which are supposed to clean the cylinders and which may, at the same time, corrode away the iron. It is an absolutely safe and sure method which demonstrates its own efficiency immediately on any car by spitting out from the exhaust the solid chunks of carbon until the pavement is covered with particles.

Then you turn the cock back to neutral where it remains ready for immediate use when you feel that the cylinders again need attention.

Added to this, you have the additional advantage of being able to turn the three-way cock to another position, permitting a slight inflow of air or moisture in warm weather.

The **Hart-Bell Carbon Remover** does **not** admit water to the manifold. **It injects atomized vapor so fine that in the cylinder it becomes superheated steam.**

Would a device which absolutely eliminates carbon forever from your motor be worth the price of one cleaning, $5?

Let us send you our enlightening booklet which is based upon the most advanced engineering practice.

How to Keep Out of Trouble

Getting out of trouble is a matter of wits —Keeping out of it, a matter of wisdom

When your Ford gets cranky and hard to start—loses its power and flexibility, its coils need adjustment. With nothing to go by that you can see or hear, getting a set of Ford coils in good adjustment is a harder thing to do than to regulate four clocks so they will tick in unison and keep exactly the same time.

The best adjustment possible gives relief only for the time being—the trouble will come back.

—— *The* ——

CONNECTICUT MASTER VIBRATOR

FOR FORD CARS

will not only eliminate Ford ignition troubles, but will give your motor more power, greater flexibility and marked economy in fuel. Once installed, nothing can disturb the uniformity with which it delivers a hot, fat spark accurately timed for each explosion. It is a specially designed instrument—one master coil with a single set of vibrator points to time the sparks for all four cylinders.

Easily installed on either old or new models—the only Master Vibrator on the market which affords a workmanlike installation on the new Fords now coming through.

PRICE, $9.00

The New Schrader Quick-Acting Dust-Cap

The operation of testing the air-pressure in tires having been found on occasion difficult and irksome by reason of the jamming together of the valve stem and dust cap, the firm of A. SCHRADER'S SON, Inc., have designed and placed on the market a new "Quick-Acting" Dust Cap which can be removed from the valve stem by a simple quarter turn.

The new SCHRADER "Quick-Acting" Dust Cap eliminates the work of screwing the cap down the entire length of the valve stem to the felloe of the wheel. All that is necessary is to slip the cap over the valve and turn it one-quarter turn. This locks it securely to the valve stem. To unlock, simply give one-quarter turn in the opposite direction.

HEISER'S IMPROVED CYLINDER REBORING TOOL FOR FORD ENGINES

REPAIRMAN

There has been a period in your life that you were unable to tell a valve from a spark plug, a magneto from a carburetor, or a cylinder from a piston; some one had to tell you what these parts were and their function. The troubles arising from these and other parts of a car, you have mastered, but you are still at sea if you do not understand and are not prepared to rebore and fit oversize pistons, for this is the most important repair that can be given a worn engine.

The HEISER IMPROVED CYLINDER REBORING TOOL for Ford Engines, makes a good shop out of a poor one and a better shop out a good one, but best of all, it gives the owner service. The end of this season will see one million Fords on the highways; this means many million dollars will be spent on reboring and fitting oversize pistons.

The early bird catches the worm. We furnish oversize pistons to fit the rebored cylinder, $1.50 each, Complete.

Write for further particulars about this wonderful tool.

The RIGHT and the WRONG Way

to Lubricate Transmissions

Look at these two illustrations—Study them Note the vast difference between PROBABLE lubrication with ordinary oil and POSITIVE lubrication with NON-FLUID OIL. Which depicts the actual working conditions of YOUR TRANSMISSION?

TRADE MARK REGISTERED IN

NON-FLUID OIL

UNITED STATES PATENT OFFICE

These gears are operating smoothly and silently without undue strain or wear on gear teeth. Gears are completely enveloped with "K-No. 00 Special" NON-FLUID OIL—all the time. This coating is pressure-resisting and so adhesive as to cling to gear teeth regardless of weather conditions, speed, or heat. "K-No. 00 Special" stays where put—remains on the gears and eliminates the possibitity of undue wear and abrasion—and saves power losses. It also reaches and lubricates all shaft bearings. Thus, it may be seen that the use of "K-No. 00 Special" NON-FLUID OIL for your transmission gears GUARANTEES you the most efficient and economical operation.

Now look at these gears, lubricated with oil (or grease and oil). Note how absolutely bare and unprotected the gears are. They operate with a grinding, noisy jar because what little oil they pick up is quickly thrown off. FLUID-oils and grease-compounds fail to cushion the impact of gear-teeth, thus causing wear and abrasion. Power is being wasted in this case at every revolution. A mixture of oil and grease will not help matters any, because grease settles to the bottom of gear case and only an occasional splash of oil reaches the working surface of the teeth. Furthermore, whatever oil reaches the shaft bearings quickly works out and you are in line for great trouble and expense.

Send for FREE sample can of "K-No. 00 Special" NON-FLUID OIL—and try it

Puts Oxy-Acetylene Welding Profits Within Easy Reach of Garage Owners

¶ This standard apparatus, high-grade in every particular, we furnish to garage owners for

$50.00

under a liberal trial arrangement.

¶ With this splendid outfit, any mechanic can become an expert welder within a short time. The **Searchlight Welder** is simple to operate, always dependable and will handle the widest range of work.

¶ The profits on a few repair jobs will pay its cost. Never before has an outfit as fine as this one been sold for so little money, and we are making the price very low for a definite purpose.

¶ We expect by placing many torches in garages, to make new customers for **Searchlight Acetylene.**

¶ The $50.00 price does not include tanks, which are furnished separately. Prices on application.

¶ The Searchlight Instruction Book contains many illustrations and covers in detail the oxy-acetylene process.

¶ A post-card will bring you information covering our liberal trial plan.

WARNING

To The Trade

On June 22d, 1915, we were granted U. S. Patent No. 1143909, covering the

Tapered Spiral Filament

In Lamp Manufacture

ADVANTAGES—

The Ideal AUTOMOBILE HEADLIGHT

Because:

More concentrated and uniform light, therefore vastly better focusing qualities than any other coil filament on the market.

The illumination of the leg through the center of the tapered spiral concentrates the entire strength of the current into a single-point light of vivid intensity.

This Patent, Applied For On March 14, 1914, Will Be Protected By Us To The Full Extent Of The Law.

All Persons are Warned Against the Manufacture, Use, Possession or Sale of any Infringement upon these Patent Rights.

JAEGER'S NITROS

Oxy-Acetylene Welding Pays Big Profits to Garage Owners

If you are not equipped to do Oxy-Acetylene repairs in your own shop, you're losing good, legitimate profits.

With the welding process, you can save money for yourself by cutting repair costs. You avoid unpleasant delays, waiting for replacements. Immediate repairs make pleased patrons. Damaged parts are quickly and easily made good as new at small cost. Most of these repairs would be impossible by any other method.

Even at the most moderate charges, the profits from this end of your business are too big to be neglected.

The daily use of the welding equipment requires that it be simple, efficient, portable and economical in operation. We furnish, at low cost, a thoroughly high-grade welding apparatus for $60.00. The average user will also need gas cylinders, which are extra, and about $10.00 worth of welding supplies.

If you use Acetylene for ANY purpose, you can secure added efficiency and wider scope of operations possible, by using

PREST-O-LITE

DISSOLVED ACETYLENE—(Ready-made Carbide Gas)

Prest-O-Lite Acetylene Service furnishes the highest grade of Dissolved Acetylene in portable cylinders, used as conveniently as you use cylinders of oxygen. Saves the large initial outlay and heavy depreciation, trouble and inconvenience of making crude Acetylene in carbide generators. Besides, Prest-O-Lite Dissolved Acetylene is perfectly dried, cleaned, and purified—makes better welds and is cheaper to use.

A GOOD BUSINESS OPPORTUNITY FOR ENTERPRISING MEN

Doing Oxy-Acetylene welding for others is a highly profitable business. The cost of equipment is low Immense and growing demand assures profitable operation right at the start.

GET YOUR SHARE OF WELDING PROFITS

Write us for highly instructive literature on Oxy-Acetylene Welding and Cutting. If you are too busy to write a letter, your name on the margin of this page will do. See what others are doing with the Prest-O-Lite Welding Process—how you can add to your profits by adding the up-to-date methods in YOUR shop.

DASHBOARD OIL GAUGE

How many of you had to get under your car to see how much oil there was in the engine, and after putting in more oil, forgot to close the stop-cocks, then after getting away a few miles from a garage, only to find that the oil had all leaked out? This can be overcome by using one of our dashboard oil gauges, which will show you at a glance from your seat how much oil there is in your engine.

Attached in place of lower pet cock in crank case as indicated in illustration above; no holes to drill or other alteration necessary. Made of heavy brass and reinforced.

List Price, $2.50

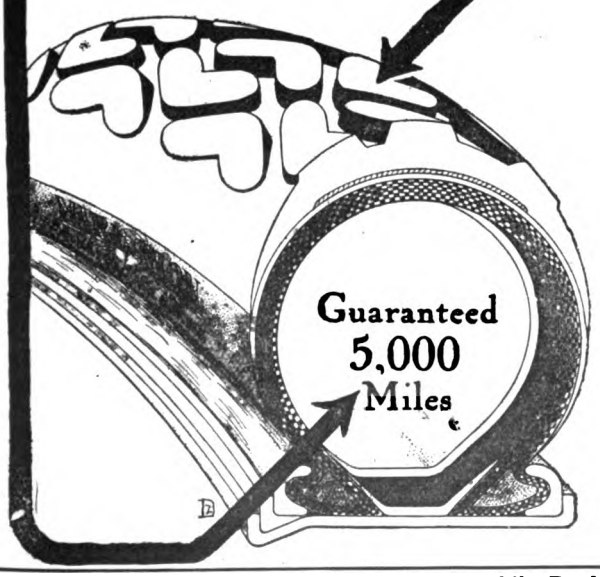
MARATHON TIRES

Get and Hold Business

To the Dealer who is desirous of securing the better class of trade—who is seeking to establish for himself a name for quality and fair dealing the big opportunity lies in



MARATHON TIRES

Marathon Tires are built entirely by hand of the finest materials obtainable and are vulcanized by the Unit-Cure Wrapped-Tread method.

Our exclusive agency proposition by which the dealer controls his own territory will open up new avenues of profit for you.

Your inquiry will bring you full particulars as to our selling plan and Individual Dealer's co-operation.

THE MARATHON TIRE & RUBBER CO.
CUYAHOGA FALLS,
OHIO

"A Twist of the Wrist"

—That's how simple it is to put in or take out the Henemier Valve—no tools required, and so simple in construction that there's nothing to get out of order.

Stem showing Henemier Valve in position.

The Henemier Valve is the long looked-for improvement on one of the most vital parts of the automobile.

The best tire in the world can't produce its maximum mileage unless the "air" is kept in the tire and kept at the right pressure after it is in. And the every-day tire valve, which hasn't changed a bit in form or principle since it was first made for bicycle tires, doesn't keep all the air in the tire all the time.

The HENEMIER VALVE-INSIDE

MADE UNDER U.S. LETTERS PATENT

keeps the air in all the time—keeps the pressure up all the time—keeps it properly inflated all the time.

Fits all standard stems and pump connections. Accepts and discharges air faster than any other valve.

Write for sample—test it yourself—

then you will have a pretty good idea of what we are telling you to tell your customers to buy.

The illustrations will give you a very fair idea of the Henemier Valve, and when you send for a sample you will be able to appreciate the advantages of the Henemier Valve over all others in just about one-half of a minute.

Packed 100 in a box, to retail at 5 cents each. Write for samples and trade discounts today to

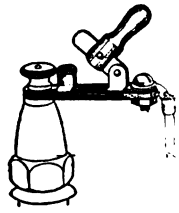
A Few Good Ones



from the

C·B

Line of

Self Selling Specialties

The Spark Plug Switch

A simple, inexpensive attachment that is a boon to every man or woman running a car.

Attach it in a minute to the spark plug—it is a permanent fixture.

One person can test each cylinder while the engine is running. No tools required. No soiling of hands.

It tells if batteries are weak, if magneto is not delivering proper spark, if wire is broken, or why power is lost, and where.

Retails at 25¢ each. If dealer does not carry it send $1 for equipment for four cylinder car, or $1.50 for six cylinder, and so on.

The C. B. Spark Plug Switch makes a Peerless out of a Ford. It is a wonder worker. It is folly to do without it at any price, especially at the low price we charge. Write to-day.

The Coil Type Anti-Rattle

Every Ford owner needs this anti-rattle. It is inexpensive. It stops all rattle. It helps open the door. Attached in a minute, it outlives the car. Price, at retail, 20¢ each (screws included). Sent direct if dealer does not carry it. Over 200,000 sold already.

The Flat Type Anti-Rattle

Eliminates rattle in doors and hood on all cars having door-stop. Throws open door when unlatched. In use all over the country. Easily attached. Lasts as long as the car. Once tried, always used.

Retail price, 25¢ each (screws included). Sent direct if dealer does not carry it.

Good also for house doors and windows.

"SAFETY FIRST"

The Midget Electric Hand Lamp

Handle and bulb attached in a minute to any dry battery. Highly enameled reflector gives far flashing qualities and bright, intense light.

Take it anywhere, stand it anywhere. Always ready. Strong and compact. Lasts a lifetime.

Price complete without battery, 75¢. Sent on receipt of order if dealer does not carry it.

Why try to get along without it when the cost is so small? Everybody should have it handy, and everybody can. Write to-day.

TO DEALERS: *Over $15,000,000 will be refunded Ford Owners August 1st. Don't forget that C. B. Self-Selling specialties are always in demand.*

TO CAR OWNERS: All our specialties for automobiles are labor and temper savers as well as utilities of a scientific nature—never come back from the user. If your dealer does not carry them, send your order direct, and send in his name. We ship promptly.

Goodrich Safety Tread Tires

Best in the Long Run

Cut This Coupon and get our Free Booklet that Dealers Everywhere are Talking About.

Some manufacturers and dealers questioned our judgment when we not only improved our 1915 model

C. C. Shock Absorber

but also reduced the price of our heavy car type to

$10.00 for set of two. Model for FORD,

$4.50 for set of two, $8.00 for set of four.

Our dealer aid booklet, "Proof of Profits," explains our attitude—tells why so many of our dealers are making more dollars profit this year than last by selling C. C. Shock Absorber quality at C. C. price.

Of course, you know that all working parts of C. C. are specially heat-treated steel—that C. C. stand abuse and are sold with the Cox guarantee, but you should also know why C. C. dealers are making more dollars profit.

Better fill out and send us this coupon today.

TRADE APCO MARK

SIDE TIRE HOLDERS

FOR FORD RUNNING BOARDS

There are so many new rear tire holders on the market that the public is inclined to overlook the good points in favor of a side tire carrier. Absolutely the only advantage of having the tires on the back of the car is that of balance, and as a pair of shoes weigh but 20 lbs. this is purely an imaginary one. There are hundreds of reasons, however, why you should use **APCO** Side Tire Holders, and the following are a few, any one of which is sufficient for you to decide in their favor.

1. They keep the tires clean. 2. They keep the tires away from the hot exhaust. 3. The tires can be removed in five seconds and replaced in same time. 4. They cannot be lost off the car. 5. They are much neater in appearance. 6. They can be installed in ten minutes. 7. With them it is possible to carry a trunk at the rear. 8. They make unnecessary the changing of tail light location. 9. They weigh seven pounds less than the lightest rear holder on the market. 10. There are no straps to lose or break. 11. Price is the lowest of any tire holder on the market, irrespective of advantages. 12. Special catch on top bracket locks automatically when closed and lock need not be used unless wanted. 13. Screws that hold bracket to body cannot be removed with tires in place. 14. Lock is solid brass, mail type, which opens automatically when key is turned. 15. Lock clasp is rubber covered to prevent rattle. Furnished in black enamel only. Packed in corrugated cartons 6"x11"x7½" and weighs seven pounds. Complete with bolts, screws and lock, made in two sizes. Regular carries two shoes and Special carries one shoe 3½" or 4", or 3½" shoe on demountable rim or wire wheels.

The advantages of the demountable rim or detachable wire wheel as applies to the Ford car are limited, and when the extra tire is securely strapped to the standard side or rear tire holder, it is more work to detach it than it is to change the tire. The new **APCO** holder simply requires the turning of a key and the extra tire is at your service, and by reversing the operation the other tire is securely locked in position—on the running board where you can see it.

Your insurance policy does not cover the theft of extra shoes unless they are valued at more than $25, but an **APCO** tire holder is theft proof and it is yours for life for $2.

$2.00

AUTO PARTS CO., - PROVIDENCE, R. I.

AMERICAN
AUTO WHISTLE

SERVES TWO PURPOSES

A Loud Warning Signal That Also Protects Your Car From Thieves

When leaving your car you simply take the key with you, which leaves the whistle open so that your engine cannot be started without the same blowing loud enough to be heard blocks away.

It is a whistle that will blow for you as long as your engine goes, with just a kick of your foot, thereby giving you the use of your hands and feet in case of accident.
It is a whistle that will prove it was blowing at time of accident, if necessary.
It is a whistle that will tell you if a cylinder is leaking or skipping on your engine.
It is a whistle that cleans itself. *Write for prices and full particulars.*

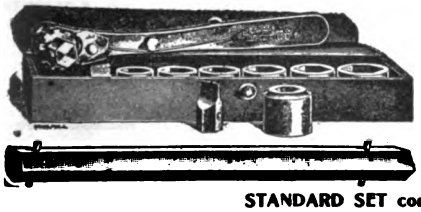
SPITLER PUNCTURE PLUGS

(Patented May 11th, 1915.)

The Spitler Puncture Plug repairs punctures in automobile and motor cycle inner tubes quickly, and without the use of cement, assuring a safe, permanent and economical repair.

The operation is so simple that a lady can make the repair without soiling her hands.

The plug can easily be taken out and used over again. A permanent repair in one minute.



To insert The Spitler Puncture Plug into the puncture, fold the inner tube at right angles and cut the corner thus formed, making the puncture large enough to easily insert the plug. Wet the tube before inserting plug.

Place the base of plug on edge and by stretching the tube at point of puncture, the plug slides in like a button in your coat. Then place cap over discs and screw lock cap firmly.

This device fits the inner tube in a manner which prevents any possibility of injury to the shoe on tube. *Write for Circular.*

PRICE:—Automobile Plugs one inch, four to set, $1.00 per set.
—Motorcycle Plugs ¾ inch, four to set, 75c. per set.

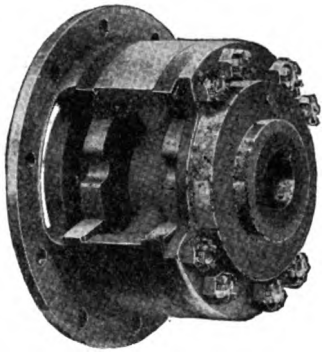
EASY TO OPERATE

NEEDS NO EXPERIENCE

Free Your Ford



— FROM —

Sidesway, Skidding or Stalling

That's what thousands of Ford owners are doing by means of the Gearless Differential.

"Adds fifty per cent to comfort and cuts my upkeep cost"—that is a sample of what users are writing us from all over the country.

And it's true. Ask any engineer about the differential gears in your car. Learn how they tend to make your tires scrape along the ground when the road's uneven—how they waste power by failing to deliver it where it's needed. The

Bailey Gearless Differential

is the first improvement in the standard type of differential in 15 years. That is what the Engineering Department of the New Process Gear Corporation — the world's largest makers of differential gears—reported recently.

Positive drive on both rear wheels. Power always delivered to the wheel with positive road traction. In ordinary driving you get all the advantages of a solid axle.

Pays for itself quickly in saving—worth many times its cost in added comfort and safety. Sent complete, ready to install. Circular on request.

FORD DEALERS!

We are receiving hundreds of inquiries from Ford owners—only a small percentage of the actual sales possibilities once the value of the Bailey Gearless Differential is demonstrated to them.

There is good profit for you—and we have a no-risk proposition that's a winner. Write for it.

Running Board Braces.

Make Your Ford as Quiet as an Electric and as STRONG as a Truck.

DOTTED LINE shows the teeter and buckle as you step on your car now.
SOLID LINE shows how rigid *CASEY* braces are guaranteed to make it.

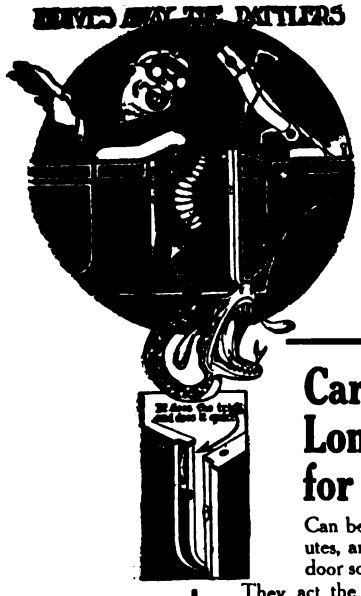
Why not stop that rocking and teetering in your Automobile? Every time you or one of your passengers step into or out of your car (as illustrated by the dotted lines above) your truss rods, frame and fenders are strained into most strenuous contortions and then quickly released back into normal position again.

Is it, therefore, any wonder the mud guards become loosened at their fastenings and rattle or the truss rods snap off at the threaded ends?

Two dollars invested in a pair of *Casey* Braces will positively insure your Car against this abuse during its entire life. Will make your Running Boards STRONG and QUIET.

You can safely carry battery and tool boxes, entire camping or touring outfits or other loads on your running boards and there will be no strain or pull on your rods or fenders to make them LOOSE and NOISY.

The three-point suspension as used in bridge building and other metal construction, is an accepted standard, because it is scientifically right. Your Automobile will be rigid because the strain is equally distributed between the three points of support as indicated by the three arrows in the illustration, and jumping on the step with both feet cannot strain your Chassis in the least.



You can easily attach these braces in a few minutes yourself, and they will positively do wonders for your car. No drilling or fitting necessary. All you need is a wrench. Shipping weight, 4 pounds.

***Casey* Running Board Braces,** $2. per pair complete.....

All Cash Orders received for the next 30 days will be sent prepaid.

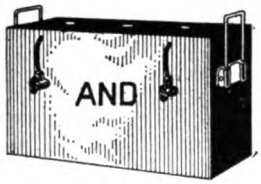
STOP THAT LEAK

You are using too much oil!
You are wasting gasoline!
You are not getting enough power!
DON'T THE UP-KEEP GIVE YOU THE BLUES?

Trade Mark

Patent Applied For

AUTO OUTING CO. (Buick Distributors), Baltimore, Md., writes:—When you called 18 months ago about "NO-LEAK-O" Rings, we were not interested. Buick cars were giving such good service, we could not see the need of new rings. You made such strong claims that we tried a set. The increase in power, saving of oil and gasoline was a surprise to us. Our repeated orders for hundreds of "NO-LEAK-O" Rings speak stronger than we can write.



"NO-LEAK-O" piston rings have grooves which CONTROL THE OIL, giving perfect lubrication without waste. No smoke. No carbon. No oily spark plugs. No grinding of valves. We absolutely guarantee each ring for QUALITY, ACCURACY, and SATISFACTORY service. ONE PIECE, LOW COST, HIGH EFFICIENCY. Carbon eliminated by controlling the oil.

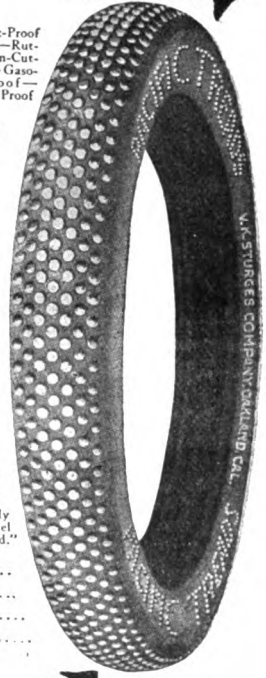
From This

Don't Throw Away Your Worn Tires Like So Much Junk!

It is unnecessary, highly extravagant, and altogether uncalled for—**Retread them at a LOW COST with "Pacific Fibre Treads" and cut down your tire expense $50 to $500 a year**—Our free booklet tells you how.



To

In 15 Minutes your old tires can be made good for

5000 Miles more

—Guaranteed
—Puncture-Proof

Blowout-Proof —Skid-Proof—Rut-Cut-Proof—Rim-Cut-Proof—Oil-Proof—Gasoline-Proof—Tear-Proof—Road-Proof—Trouble-Proof

"Pacific Treads"
Are Not Leather Treads

Leather Treads, processed, treated or tanned as many times as you can imagine, will stretch and sag and being non-resilient can never resume their original shape again on the tire, once they are stretched. Pacific Treads on the other hand fit your tire like a glove and expand or contract evenly, smoothly and instantly—as little or as much as is required—never any more.

We Ship on Approval—Pay Express Charges—Ask no Deposit

Pacific Treads will save every motorist who uses them time, worry and expense. We will prove it to you at our own expense if you will fill out the coupon below. Mail it today.

Special Discount Offered to motorists in new territory on first shipment.

"There's An Inner Tube the Boy Saved from the Junk Pile with TIRE-DOH."

Don't throw away inner tubes because they look beyond repair. When we tell you

TIRE-DOH

has permanently repaired a 37-inch tear in an inner tube you will better appreciate our claim that it is the most wonderful puncture and blowout repair on the market.

Tire-Doh will save you many dollars tire expense in repairing both tubes and casings. Anyone can use it—on the road or in the garage—and the average inner-tube puncture repaired with Tire-Doh costs less than 2 cents.

TIRE-DOH REPAIRS ARE PERMANENT

A Tire-Doh repair is as tough and elastic as the repaired surface.

Tire-Doh used to fill cuts and holes in casings will prevent water and dirt from reaching and rotting the fabric—thus doubling your tire mileage.

Tire-Doh also permanently mends other rubber articles—rubber boots, hot water bags, etc.

AT YOUR DEALER'S OR DIRECT FROM US, $1.00

DEALERS—Unless you handle Tire-Doh your stock is not complete. It is the standard repair and is advertised.

SPRINGFIELD, OHIO

CITRUS
CUBA

Wonderfully rich land, good water, good title. Outdoor life the year 'round. A ten acre grape fruit grove will pay you $2,500 per annum for life. Eastern Cuba is to be the great winter playground of the American. The land is so fertile and accessible that fortunes are to be made in fruits and vegetables. Great country to relieve and cure rheumatism, nervous and respiratory diseases.

Present price of land $50 per acre. No frost and no irrigation or fertilization required. The young man's opportunity and the old man's paradise.

The grape fruit raised here surpasses in flavor and quality anything grown in Florida or Southern California.

The most delightful place in the world for a winter home, and very accessible. Boats sail from New York to all the principal ports, and at very reasonable rates.

PERFECT MANUFACTURING COMPANY
ALBANY, N. Y.

"There's a mighty big difference in lubricators!"

Don't blame your car for what it can't help. Many a car is inefficient only because its lubrication is bad. Try Badger Gear Compound **just once** and notice the difference.

BADGER Gear Compound
Is "Always on the Teeth"

It never runs thin and stays where you put it. Will not pack the sides of the gear case. Nothing like it for minimizing wear and quieting rear axles and transmissions. **Every ounce lubricates.** Learn more about this power-saving lubricant—also about the popular F. V. Motor Oil and Badger Lubricants. Ask your dealer or write us. *Dealers, write us*

WADHAMS OIL COMPANY, Milwaukee, Wis.
Coast Distributors: Wadhams Oil Company of Washington, Seattle, Wash., and Vancouver.

DIXON'S

GRAPHITE GREASE No. 677

For Transmissions and Differentials

does the trick. It is highest grade mineral grease and Dixon's selected flake motor graphite, the only form of graphite that will not ball-up or pack under pressure. It covers the bearings with a durable, oily veneer that keeps metal from metal and lets graphite ride on graphite.

The Foundation of this Tire

is just as good as the day it was bought. Any tire with good fabric, whether there is any rubber on the outside or not, is suitable for the

TRIPLE TREAD PROCESS

The Triple Tread is the only tire protector made

that does not depend on inflation, rim pressure or mechanical means to hold it in place, so that the style of bead on your tires cannot affect the success of their treatment.

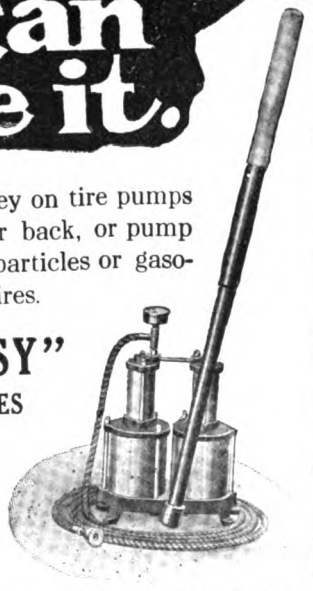
In Vulcanizing the Triple Tread on your Tire

we are able to fill the pores of the leather with rubber, making it waterproof, so that by bringing the leather down the sides and over the bead of the case, covering it completely, we are able to keep dirt and water from getting under the tread to rot the fabric, and also to strengthen the sides and bead of the tire.

Write for our booklet,

"Worn Out Tires Made New."

Please mention the size of your tires.



TRIPLE TREAD MFG. CO.

1542 MICHIGAN AVENUE CHICAGO

Factories: San Francisco, Chicago, Winnipeg

At Our Risk—You Can Prove it.

Don't waste good money on tire pumps that either break your back, or pump **Rubber Rotting** oil particles or gasoline fumes into your tires.

"DEAD EASY"

TAKE NO CHANCES

At our risk you can prove that the "Dead Easy" is quicker, safer, easier and cheaper than any other tire pump, either engine drive or hand power.

Convenient to carry with any car, it is always ready for instant service. The gauge showing exact tire pressure, there is no guesswork—and it's "Dead Easy."

FREE TRIAL OFFER

Write *today*, NOW, for fifteen-day—no-money-in-advance—free trial offer.

GLOBE MANUFACTURING COMPANY

BATTLE CREEK, MICH., U. S. A.

Allen This Tire Pressure Gauge Will Save Tire Expense

Careful, thorough investigation has shown that over 75 per cent. of all tire troubles is directly traceable to under-inflation. This can easily be avoided by testing the air pressure in the tire with the

ALLEN TYROMETER

TIRE PRESSURE GAUGE

This handy, accurate, guaranteed gauge is 4½ inches long, made of heavily nickeled brass tubing, with sliding band which holds the indication as long as desired —clip attached for carrying in pocket.

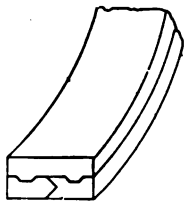
Sta-Tite Piston Rings

Are Mechanically Efficient



Sta-Tite Piston Rings are made up of three individual interlocking rings, grooved together to give Maximum Flexibility and Resiliency.

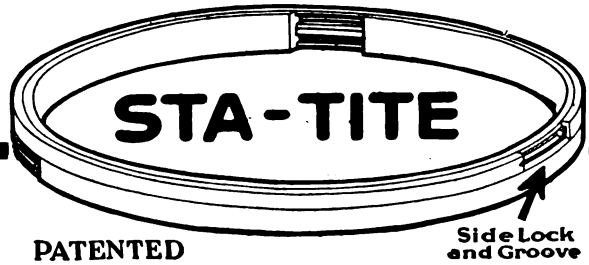
The wonderful resiliency of the Sta-Tite Ring enables it to automatically adjust itself to the width of the Piston Ring Groove.

Leakage of Compression and Oil is a mechanical Impossibility.

"Piston Ring Service Is the Key to Perfect Compression."
—Efficiency Ed.

This cross-section shows the Groove Construction which prevents the sections from slipping out of place or "riding" the pins and scoring the cylinder walls.

Prevents the "vents" or slot openings from getting in line and allowing the leakage of Power and Compression.



Install a complete set of these Mechanically Efficient Piston Rings and notice the Increased Efficiency of your Car.

Special Inducements to Dealers and Agents.

Rings in All Sizes. **Write for Literature.**

Puts Pep In Motors

You men who sell or repair automobiles, get wise to the wonderful three-piece piston ring that puts PEP in gasoline motors. Ever-Tight is its name, and ever tight it is—always. New motors equipped with this ring give better service, and worn motors repaired with it are practically as good as new.

EVER-TIGHT

Piston Ring—"For Leaky Cylinders"

is composed of three perfectly grooved sections that play upon each other easily. It is so flexible that it instantly takes the form of an out-of-round cylinder, prevents power-waste, lessens friction and keeps oil out of the combustion chamber. This means full motor power and no carbon.

Ever-Tight is the only satisfactory three-piece ring made. Repairmen should write if local dealers do not carry it. We want jobbers and dealers in every city and town. *Write for particulars.*

NATIONAL RUBBER TIREFILLER

An ingenious treatment of small Pure Rubber particles which holds them together in solid form—solid enough to carry the heaviest load your engine will pull—resilient enough to give that "ON AIR" feeling that brought popularity to pneumatics—cannot puncture, rim cut nor blow out—makes your tires cost less by wearing longer.

National Rubber Tirefiller in your tires is like Tire Life Insurance Policies—they insure you more miles out of your tires—complete freedom from all tire trouble—against serious accidents from blown out tires and the real tire service you are entitled to.

It eliminates the delicate and expensive inner tube entirely—it replaces uncertainty with certainty and makes your car absolutely dependable. Let us send you small sample and tell you more about them.

NATIONAL RUBBER FILLER COMPANY,
208 College Street, MIDLOTHIAN, TEXAS.

ZENITH CARBURETOR FOR FORDS

You can give to your Ford the same flexibility, power and economy that this carburetor has given to the world's best cars. That unpleasant jerky engine-pull when changing from low to high or when throttled down is entirely eliminated. Insures easy starting and wonderful economy.

There are no complicated adjustments to tinker with and no moving parts to wear out.

The Compound Nozzle of the Zenith regulates the flow of gasoline at every engine speed and under any climatic condition, insuring perfect vaporization at all times.

The choice of the world's best automobile engineers is certainly worth this trial offer.

$20
COMPLETE
Including Manifold and Hot-Air Tube

TRIAL OFFER

If after 30 days' trial you find that the Zenith Ford Carburetor is not well worth the purchase price—return it at our expense and get your money back.

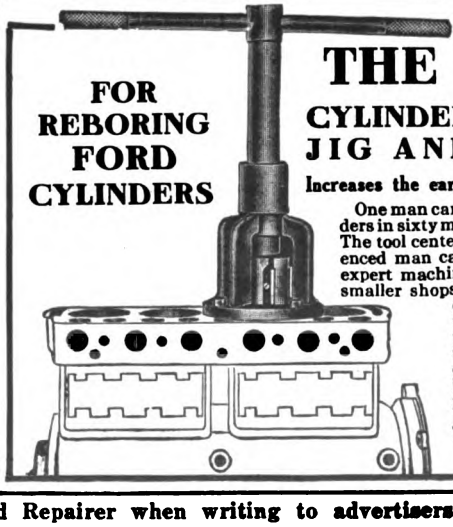
Vulcanizing Cement
Sell Goodyear C-15



Trade is often won, held and built on little things like a tube patch or can of cement. Confidence in the accessory line you carry—and in the service you give—is the factor that wins for you all the time. All Goodyear Accessories—22 Tire Savers—are up to the master standard set by Goodyear Automobile Tires. Goodyear C-15 Vulcanizing Cement is the most practical you can sell. It is of exceedingly heavy consistency, and for ordinary use can be thinned with a 72 test gasoline. It cures black.

Learn more about Goodyear Accessories. Remember—there is good profit in accessories that deliver and stay sold through extra quality. Write today for dealer's proposition. Address Desk 184

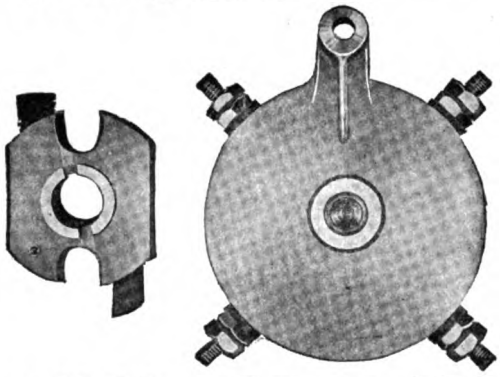
FOR REBORING FORD CYLINDERS

THE DAVIS
CYLINDER REBORING JIG AND REAMER

Increases the earning power of your shop



One man can rebore a set of four cylinders in sixty minutes with this machine. The tool centers itself, and an inexperienced man can do as good a job as an expert machinist. With this tool the smaller shops and garages can rebore cylinders and guarantee the work to be as good as the larger dealers with their expensive machinery. Makes the motor better than new. Write for price and full particulars.

AT LAST!

A PERFECT TIMER FOR FORD CARS

Price $2.25 **Guaranteed for Life**

With this Timer you get a wipe contact instead of a rolling contact. This contact is made by a low resistance composition brush which makes a positive wipe contact. Furthermore, there is a felt wiper which travels ahead of the brush, which positively keeps contacts clean at all times.

The Rotor in this Timer is in no way affected by centrifugal force, due to the fact that all revolving parts are contained within the rotating unit.

Each Black Circle Means a Satisfied Customer

The growing sales of ENDURA—the water-tight, oil-tight, gasoline-tight sheet packing—indicate that garagemen and dealers are feeling the good effects of putting *special-purpose* packing into cars where it is *needed.* And the fact that ENDURA weighs but *half* as much as other packings that *cannot do the same work as well* suggests the profits and benefits arising from its use. Send this coupon for booklet containing chart, and free samples of ENDURA SHEET PACKING.

For Every Garage

The FOSNACHT VALVE RESEATER is the most convenient, quickest and most accurate tool for cutting valves and valve seats. Every garage using this appliance is delighted with the speed—the cleanliness—and the general satisfaction afforded by the FOSNACHT. Does the work in a quarter the time needed by hand. No expert required to operate it—no emery—no dirt—no tearing apart of motor. The

FOSNACHT Valve Reseater

should be in every garage. Attracts repair work by its ability to turn out jobs speedily and exactly. Holds business for owners. The FOSNACHT VALVE RESEATER is a *real* profit builder. Not a cheap machine—sold at **$25.00, less 5% discount for cash.** The high quality of this unusual tool makes the price a very low one. We believe in quality—quality is remembered long after price is forgotten. The FOSNACHT will pay for itself in a short time through the increase in trade it will bring.

Our free booklet is a map in words and pictures showing the direct route to more and better business. Get the book *to-day* by sending your name on a post card. Address

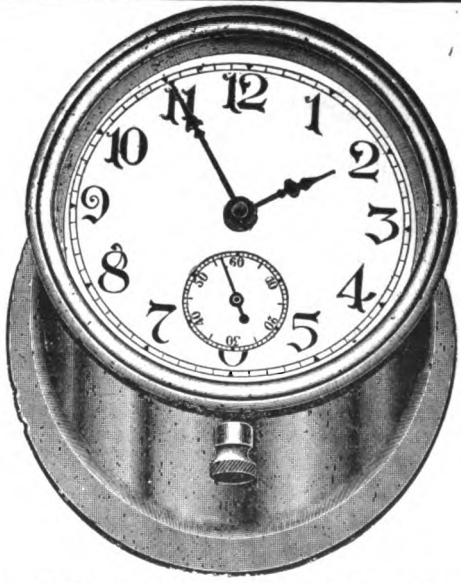
AUTOMOBILE SUPPLY MANUFACTURING CO.
220 TAAFFE PLACE BROOKLYN, N. Y.
The Largest Manufacturer of Auto-Horns in the World

Every Repair Shop or Garage
SHOULD HAVE A CLOCK.

We have recently made very favorable arrangements with one of the largest clock companies in this country by which we are enabled to offer to our readers in the United States or its territories a **Regulator Eight Day Calendar Clock** 38½ inches high, with a 12 inch dial, finished in **Oak** or **hand-rubbed Mahogany**, with a subscription to the **Automobile Dealer and Repairer** for one year, at the very low rate of **$3.90.** This clock cannot be sent to any foreign country except Canada, and Canadian subscribers must send **50 cents** more to cover extra postage on the paper.



Every repair shop, garage or dealer's office should have one of these clocks. It will give you the time of day correctly and the day of the month.

The engraving shown gives the correct appearance of this clock.

This offer is good for either old or new subscribers.

Remittances can be made in any convenient way. Be sure to state whether you want this clock in Oak or Hand-Rubbed Mahogany.

Address all orders to
THE MOTOR VEHICLE PUBLISHING CO.,
Publishers of THE AUTOMOBILE DEALER AND REPAIRER
71-73 Murray Street, NEW YORK, N. Y.

DO YOU WANT A MOTOR CLOCK

For your car, and a good one? The clock illustrated in this connection is manufactured by one of the most reliable clock companies in the country and is warranted in every respect. It is not liable to get out of order. It has interchangeable parts. It is the product of skilled labor combined with the most improved Waltham Automatic Machines. This clock is 3¾ inches high, and has a Porcelain dial 2½ inches in diameter. It has a one day movement with second hand. It can be furnished in burnished brass or nickel plated whichever is preferred. The arrangement we have made enables us to furnish **one of these clocks and a subscription to the Automobile Dealer and Repairer for a year** to all residents of the United States and its territories for the precise price the clock retails for, namely, **$2.50.** If an eight day clock is preferred send 50 cents extra or $3.00. Canadian subscribers should add 50 cents extra to cover the extra postage required on the **Automobile Dealer and Repairer.** This clock cannot be sent to foreign countries. The clock can safely be sent by mail and will be forwarded postage prepaid to any part of the country. Remittances can be made in any convenient way. Address

Buying Right

YOU have got to buy right in order to be able to sell right.

Of the two great business factors buying takes more brains than selling—it takes foresight and judgment beyond the mere consideration of price and profits.

This is true of handling anything the use of which makes satisfied or dissatisfied customers according to the service it delivers . . . . brake lining, for instance.

The popular demand is for Raybestos and always has been.

It is not a price product but a quality product.

People buy it because they believe it is priced right and it is guaranteed to give one full year's service whether they drive one mile or fifty thousand miles.

Most people prefer to trade where they are sure of getting good goods, reasonable prices and fair treatment.

How much foresight and how much judgment does the dealer display when a little longer discount will wean him away from handling Raybestos.

Any cut in the manufacturer's net means a cut in the quality of his goods.

Getting Raybestos list price for any brake lining that can be bought cheaper at wholesale than Raybestos is not fair treatment to the customer.

Where does anything resembling business judgment come in. What effect will such buying practice have on sales—not today, possibly, but tomorrow?

FISK NON-SKID

WITH FISK SERVICE

Buy Fisk And Get Safety, Service, Satisfaction!

WHEN you equip with Fisk Non-Skid Tires, *you have bought right!* You have bought one of the biggest values ever known; you have bought Safety, Service and Satisfaction; you have bought the best tire we have ever made.

Fisk Low Prices represent a new and wonderful standard. They enable every motorist to secure this popular and time-tested Non-Skid at a price actually lower than charged for many plain tread tires of other standard makes.

Compare these Fisk Non-Skid Low Prices With the Cost of Other Standard Treads—Non-Skid and Plain

3½x30 - $12.20	4½x34 - $27.30
4 x33 - 20.00	4½x36 - 28.70
4 x34 - 20.35	5 x37 - 33.90

Fisk Plain Tread Prices are 5% ***lower*** *than Non-Skid.*

Fisk Low Prices offer car owners an absolutely sure way to cut down tire expense. Whether you have a large or small car, the Fisk Non-Skid is the *sane* tire choice.

FISK SERVICE is conducted in the interest of all car owners. It extends to motorists the best the world affords in the way of skill, equipment and the personal interest of a thousand trained Fisk Branch employees and many thousands of selected dealers.

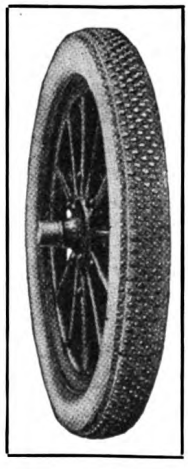
Don't Part With Your Half-Worn Tires



This picture illustrates forcibly what happens to the ordinary pneumatic tire, after 3,000 to 5,000 miles of service—often less. You get about 9c. a pound for it as junk. Now, its just as unnecessary, just as extravagant, to throw away your tires when they become tread worn or rut worn, as it is to throw away your shoes when the original sole gets thin.

What European Motorists Do

The foremost European engineers have for a long time been studying the problem of getting more miles for less dollars. With their usual painstaking scientific thoroughness, they experimented for years with leather tire protectors and steel studded Treads.

The result—for over three years European motorists have been "half-soling" their tires with steel studded Treads, just as we "half-sole" our shoes when the original sole gets thin.

These European motorists are getting from 10,000 to 15,000 miles out of ordinary pneumatic tires, while American motorists are getting from 3,000 to 5,000, and—what is just as important—have almost entirely eliminated the constant dread of punctures, blow-outs and rim-cuts!

We Brought Herr Bullerman Here

When we learned that Foreign engineers had perfected a steel studded Tread that would make a tire run at least 10,000 miles we set about finding out how they did it. Then we brought to this country probably the foremost tire engineer in Europe, Herr August Bullerman, who designed Durable Treads along the line of that foreign study and experiment; improved them by new basic patents and made them even superior to the Treads universally used by European motorists. Their success was immediate. In eight months 20,000 American motorists took advantage of this opportunity to cut down their tire expense and eliminate their tire trouble. Last year the sale of Durable Treads increased 917% in the United States alone. Over 40% of these sales were unsolicited—made through the recommendation of Durable Tread users.

Where is there an automobile accessory which has received such universal country-wide endorsement?

Save $50.00 to $200 a Year

The almost unbelievable waste in tires by the American motorist is not only national—it is vitally personal. It affects you—your pocketbook. Just consider what it would mean to you to get 10,000, 12,000 or 15,000 miles out of your rubber casings, and at the same time drive your car without the constant dread of tire trouble.

It will make your tires run two and three seasons, instead of one. It will save you from $50 to $200 a year outright in tire bills. In round numbers, it would mean a saving in tire miles sufficient to pay your yearly gas and oil bills—by the elimination of punctures, blow-outs, rim cuts and skidding—a gratification which cannot be estimated in dollars and cents.

Guaranteed 5,000 Miles Without Puncture

Durable Treads are sold under a signed guarantee for 5,000 miles of wear without puncture. This guarantee is an iron-clad agreement—as good as a government bond—and holds good whether your tires are new or old, tread worn, rut worn or rim cut. Think of it—to be able to FORGET tires! Not once will you have to get out of that car to fix a puncture and this tire vacation is guaranteed to you.

No More Skidding

Durable Treads are sure footed as a burro and they're supremely convenient.

They are studded with sharp-edged steel rivets, which dig right down through the mud and slush and get to earth every time.

In many of the larger cities of Europe, ordinances compel the use of the steel studded Treads for public safety.

Durable Treads are always on your tires—you don't need to worry about climbing out in the rain and mud to adjust your chains, and—what is more important—you receive perfect non-skid service while your tires are protected instead of injured.

We Ship on Approval

At any time the tires now on your car may meet with injury which will put them out of commission. Why wait for that to happen? We ship on approval.

Do you intend to continue allowing the junk-man to profit at your expense by carrying away in tire miles enough to pay your yearly gas and oil bills? Why not turn to your advantage the experience of European motorists? It is the same question of economy you decide when you "half-sole" your shoes instead of throwing them away when the first sole gets thin. Rubber tires cost several times as much as shoes and are certainly worthy of the same economy.

Special Discount Offer

To motorists in territories where Durable Treads have not as yet been introduced we offer a special introductory discount equal to the full dealers' profit.

Will you let us give you a demonstration at our own expense and risk? Will you let us make you an offer so fair and square that you do not stand to lose one red cent either before or after you buy?

The time for action is NOW, before the tires on your car run another week in "barefooted" condition—before you get your next puncture or blowout.

Cut out the coupon below. If you haven't a pen or pencil handy, you can fill it out afterwards, but cut it out now before you turn the page and forget. It will be the means of adding at least 5,000 miles more life to those tires on your car.

UTILITY

PRICE $10.00
Complete with
Pneu-Meter

THE ONLY TRULY AUTOMATIC TIRE PUMP ON THE MARKET

The Pneu-Meter installed on the hose line prevents over inflation as well as under inflation. Connect your pump, set your Pneu-Meter at the right pressure, start your engine and forget it.

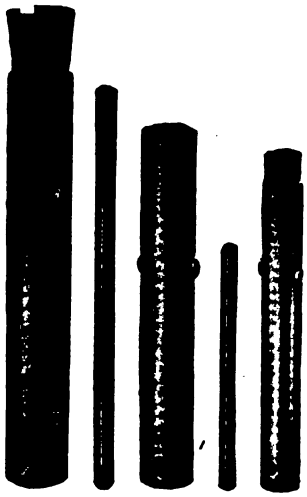
You don't have to watch your pump—the Pneu-Meter does it for you—when your tire is properly inflated, it becomes a Safety blow-off valve, using excess pressure to sound a continuous signal. **So simple a woman can work it.**

PRICE $2.00

UTILITY Jr.

PRICE $6.00
Complete with
Pneu-Meter

WHISTLING PNEU-METER



Sold separately and can be installed on the hose line of any other spark plug or gear driven pumps, garage air tanks, etc.

Absolutely accurate and cannot get out of order. Whistles loudly and can be heard fully a block away, and will continue until the engine stops.

Over and under inflation decreases the life of your tires. This is due to the use of tire pumps which are equipped with ordinary dial gauges and which at the best are inaccurate. This trouble and expense can be absolutely avoided by using **Utility Pumps equipped with Whistling Pneu-Meters.**

Smallest and fastest—simplest and best constructed pumps ever made—**absolutely safe.**

Built of rust-proof bronze, brass and nickeled steel. **LASTS A LIFETIME.**

7", 6" and 5" Long Respectively

The UTILITY Socket Wrench Set

A New Principle With Many Advantages

Has all the advantages of socket wrench sets consisting of fourteen wrenches, with none of their faults. Instant in adjustment. No screws to manipulate, or parts to get out of order. Can be applied to all shapes and kinds of nuts, immediately. Has many new features possessed by no other wrench.

SOME NEW FEATURES

Will grasp any nut instantly and requires no further effort to hold wrench in place. In removing, the jaws hold nut firmly at all times, so it cannot fall or become lost. On the other hand, nut can be placed in jaws and applied to bolt or screw when same is inaccessible to the hands.

Unequalled for use in Garages and Machine Shops, in fact, wherever nuts and bolts are used.

Will take all nuts from ⅛ to ½ inch, inclusive.

Will take all nuts used in auto work.

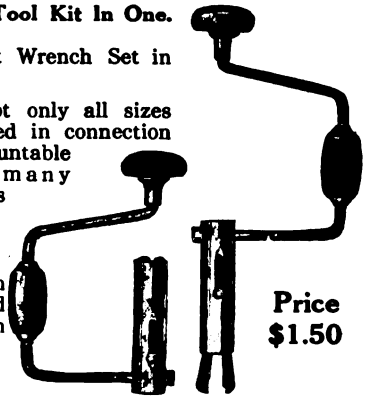
Will take hexagon nuts, square nuts, wing nuts, cock nuts, and nuts rounded or distorted by use of other wrenches.

Cannot slip and bruise fingers of workmen, as jaws have rigid bearing on four sides—the harder you pull, the harder the jaws grab the nut.

Look at its wonderful advantages and then look at the price.

Utility Wrench Set Complete, $2.50

Packed in neat canvas bag.



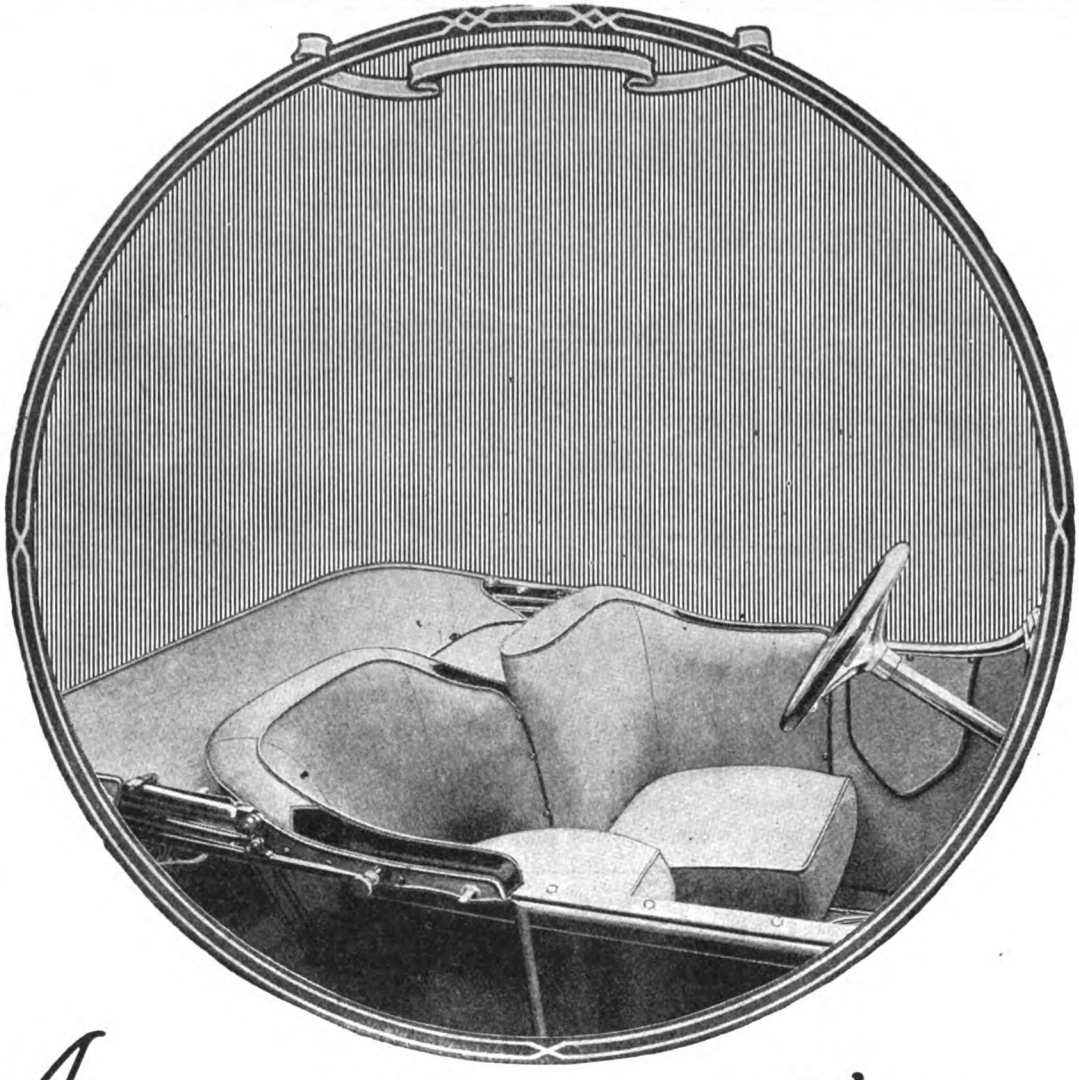
Write for Our Dealers' Proposition.

THE UTILITY DEMOUNTABLE RIM WRENCH

A Whole Tool Kit In One.

A Socket Wrench Set in itself.

Takes not only all sizes of nuts used in connection with demountable rims, but many other kinds and sizes.



Wrench can be folded when not in use.

Price $1.50

A new standard of luxury!

Write today for this catalog.

It illustrates and describes a complete line of high-grade motor car accessories. We have an attractive proposition for car dealers, accessory and supply stores and garages.

Set by Campbell Detachable Upholstery

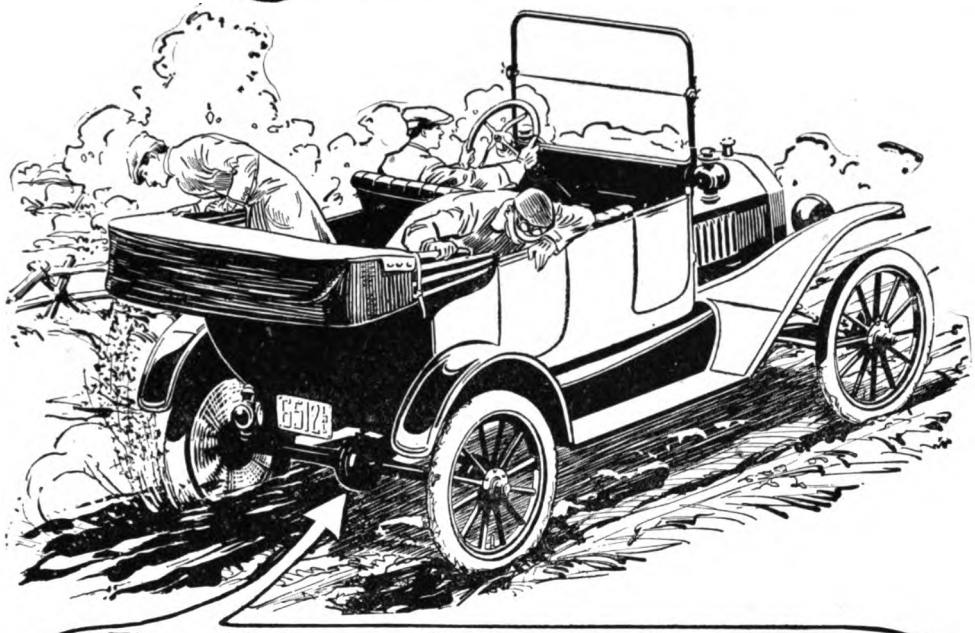
No other single article of equipment adds to the luxurious appearance of a car like Campbell Detachable Upholstery.

It is the standard by which every car is measured, for looks, for comfort, for pride of ownership.

Your car should be equipped with this beautiful accessory. It goes on over your regular upholstery and is held in place by quick detachable fasteners, so that it can be instantly removed and replaced for cleaning. Its cost is surprisingly moderate.

Every set of Campbell Detachable Upholstery is individually tailored to fit its particular make and model of car. A wide range of patterns, shades and prices offers you a selection that just suits your taste and purse.

No matter what make or model of car you own or are contemplating buying, you can have it equipped with Campbell Detachable Upholstery. A postal will bring samples of fabrics and prices. Address THE PERKINS-CAMPBELL CO., 628 Broadway, Cincinnati, Ohio. New York Office, 89 Chambers Street.



CAMPBELL

Look for the name Campbell on the fasteners. It guarantees unequalled fit, finish and luxury.

STUCK!

Through Loss of Traction Due to the inefficient old style bevel gear Differential

Familiar picture isn't it? And ten times the power wouldn't make any difference. It's not power that's needed here so much as traction. Don't blame the engine when you stick in the mud—blame the old style bevel gear differential.

Why continue to use a differential that only pulls one wheel—that carries your engine power to the wheel that has the least traction? And yet car owners and car manufacturers have had to be content with this type of differential for 15 years.

M&S DIFFERENTIAL

"Pulls Both Wheels"

U. S. Patents 1090082, patents in foreign countries. All infringments will be prosecuted.

The M. & S. Differential is made for Car Manufacturers by the Brown-Lipe-Chapin Co. of Syracuse, the world's largest makers of differentials.

The M. & S. is a spiral gear differential which distributes the engine power smoothly and evenly to both wheels.

When one wheel loses traction in mud, sand or on slippery pavements **the power goes to the wheel which has traction.** When both wheels finally find traction, the power is equally distributed. This is due to the action of the spiral gears which act automatically in the same manner as a differential lock and give all the advantages of a solid axle.

Read what "Jeffery" says

* * * * * *

During all our tests M. & S. differential never failed to work entirely satisfactory. We find that anti-skid devices are unnecessary when cars are equipped with your differential, which in itself is sufficient to warrant its use on a car and will be quickly appreciated by the public once it is demonstrated.

Furthermore, the feature that the power is applied to both wheels at all times, will take the car through roads that it would be impossible to pass through with an ordinary differential.

We are very much pleased that we were of the first to whom this new invention was submitted and that we made the test early enough so that we could get this equipment on our "Quad" for 1914 and 15.

THE THOMAS B. JEFFERY CO.

L. H. Bill

Ass't Gen'l Mgr.

Ford Cars First

The M. & S. is built and supplied as "equipment" for any new car by the Brown-Lipe-Chapin Co. The demand for the M. & S. by manufacturers so taxes the factory that it is only possible for us at this time to take care of **replacements** on Ford Cars.

The M. & S. is a **real** gear differential—not a pawl and ratchet device which drives the slow wheel only. Its construction is mechanically correct and is based on a true scientific principle.

We are now making deliveries of the M. & S. special type for Ford Cars. Ford owners can replace their present bevel gear differential. Any mechanic can install the M. & S. in a few hours. It fits perfectly in the Ford housing, using the Ford ring and pinion gears.

Nickel-steel Ring and Pinion Gears, standard ratio for Ford cars, price $6.50.

Write us for full particulars—We have an attractive agency proposition for Ford dealers or any one in a position to take care of replacements.

M. & S. GEAR COMPANY, 1036-1042 Whitney Bldg., DETROIT, MICH.

Enjoy the Scenery—Forget the Bumps

Be a Tourist—Not a mere Road Inspector

Many motorists today are slaves to the road. Their daily drives and week end trips are limited because of rough, rutty roads. They arrive home tired from being bumped around and "picking the roads"—they see nothing else all day.

Don't be a mere road inspector—equip your light, economical Ford with K-W Road Smoothers and get the greatest enjoyment and comfort.

K-W Road Smoothers give you this enviable comfort because their design combines these four factors:

1. A spring to effectively take up the shock.
2. An anti-rebound air chamber to check the rebound.
3. Anti-side motion links to prevent side rocking and swaying.
4. A construction that does not interfere with the steering.

Each of these features is in itself vital to your comfort and safety. It's only when they are combined in one device that you will get the greatest pleasure from your car. Here's how the K-W Road Smoother fills all these requirements:

The K-W Spring

A helical spring that effectively takes up the shock, made of electric smelted, chrome vanadium steel. The K-W bracket design allows almost *twice the length of spring action* or "travel" (in actual service) of any other.

The K-W Air Chamber

The anti-rebound air chamber with its smooth fitting piston acts like a door check, and gently "eases off" the rebound of the spring This is an exclusive K-W feature. Its design provides a strong, tough, self-lubricating piston, working in a dust-proof air chamber. It requires no attention.

The K-W Side Motion Links

Made of the highest grade heat-treated drop forgings of remarkable toughness. This enables them to withstand the great strain put upon them. They prevent your car from pitching, swaying or skidding while making sharp turns.

$15 SET OF FOUR
ONE FOR EACH WHEEL

K-W Bushings

All bearings are phosphor bronze throughout. That means long life.

But you can find all these vital factors *only* in K-W Road Smoothers

That is why they lengthen the life of your car, by eliminating shock and vibration. Tire economy is assured, because K-W Road Smoothers enable the wheels (not the whole body of the car) to follow the contour of the road. That means no grinding off the rubber of the tires. K-W Road Smoothers always make good because they are built with characteristic K-W Quality throughout.

But after all's been said and done, it's results that count; and the K-W guarantee covers not only workmanship and material, but *results* as well.

K-W Road Smoothers are quickly and easily attached. No holes to drill and no tools necessary except a wrench. And the final and biggest advantage you get from K-W Road Smoothers is that they increase the radius of your car's usefulness, and bring you home with that "satisfied feeling" after a day of comfortable motoring.

If your dealer can't supply you, sent prepaid upon receipt of price.

What's the Answer to the Touring Question?

But they can't give you the greatest enjoyment the most comfort—and freedom from excessive tire bills—unless they're on your car.

IF ALL roads were smooth as billiard tables; if there were no ruts or thank-ye-ma'ams—no tracks, cobblestones or rough streets to jolt and jar; if all roads were ideal it would not be necessary to equip with strong, sturdy and rugged Miller Tires.

But roads are far from being ideal. The man who wants the most pleasure from his car, must select the tire built to give him the utmost in mileage, safety and service under all road conditions.

All Roads look alike to Miller Tires

because the exclusive Miller Method of building tires does not cook the life out of either fabric or rubber in vulcanizing! Life in the cotton fabric means miles on the road. ***The Miller Method retains the natural vegetable wax and oil in the cotton fibre for wear in your tire.***

This natural lubricant carbonizes at 240 degrees. The old method of vulcanizing requires about 287 degrees to properly vulcanize a tire. And a brittle and lifeless fabric, with the power of resistance gone, results in short mileage on the road.

But the Miller Method of vulcanizing with a low degree of heat—overcomes all that.

And just as this exclusive Method retains the natural vegetable wax and oil in the fabric, so does it conserve all the toughness and wearing qualities in the rubber. Thus it makes a rugged unit of both rubber and fabric—without carbonizing the wax and oil in the fabric—or cooking the native endurance out of the rubber.

The result is a tire that insures practical immunity from blowouts and irritating road-side repairs.

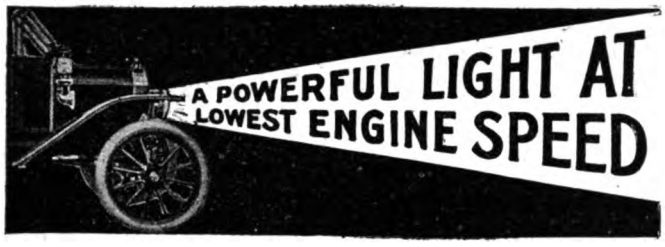
Get yours from the Miller dealer today, and make touring what it should be—a constant pleasure.

If you don't know the Miller Dealer in your town, it will pay you to write us.

The Miller Rubber Co., Akron, U. S. A.

Distributors in the Principal Cities

MILLER



Miller **Geared-to-the-road** Tires gear your car to the road through mud, sand or slush. **With Miller tires on your car you're in control. Its tread is an integral part of the tire and retains its safety features until the entire tire is worn out.** The greater mileage you get from them, will make your choice of Miller Tires an economy, as well as a permanent safeguard.

MILLER TUBES answer the tube question.

At Last! What All Ford Owners Have Long Waited For

THE NEW YORK AUTOMATIC HEAD LIGHT CONTROLLER FOR FORD CARS

PRICE $5.00

Patents Pending

A LIGHT EQUALLY AS POWERFUL AS $50.00 BATTERY SYSTEMS

Delivers a powerful light at the lowest engine speed. Uses the Regular Ford magneto, requiring no batteries or complications. **Entirely automatic in its operation**—no belts, gears or movable connections to the engine are employed. **It also prevents the bulbs from becoming burned out at excessive engine speed.** This is positively the first and only solution to the electric head light problem on Ford cars. We furnish necessary wires already connected so that anyone can install in ten minutes by the simple removal and replacing of one bolt.

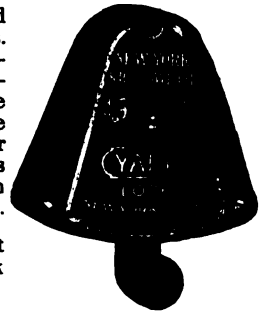
You need one—Why delay. Send us $5.00 with the understanding that you may return the device if you desire.

Install a

New York Master Vibrator on Your Ford Car

Price $8.00 at Your Dealer's

and enjoy the smooth, evenly applied power so noticeable in six-cylinder engines.



It is immaterial if your car is the latest or oldest model. You need our master vibrator, as it dispenses with all coil adjustments and replacements, and insures easy starting, a hot, perfectly timed spark under all conditions, and entire freedom from ignition troubles. It has for the past six years proven itself to be superior to any existing type. Though many times imitated it has never been equalled and stands to-day the best in its class at any price.

With fittings to install on the new 1915 models.

Prevent your Ford from being stolen by buying

OUR NEW YORK KICK SWITCH WITH YALE LOCK—PRICE $2.50

which fits the new Ford metal or wood coil boxes. This is a handsomely constructed kick switch containing a genuine Yale Lock, which affords the convenience of the regular Kick Switch, but possesses the locking feature which is found in no other type.

Anyone can install—Remit $2.50 today—Money back if not satisfactory.

Two Ignition Systems for Ford Cars

The New York UNI-Coil Ignition System for Ford Cars. Price $15.00

Operated by the Ford Fly Wheel Magneto (or Battery).

This system is primarily intended to operate on the Ford fly wheel magneto. It consists of a well-made elevating gear bracket upon which our Combined Timer and high tension Distributor is mounted. The Distributor is of the most simple construction containing the essentials of the high tension magneto. It uses one unit equipped with vibrator of your regular Ford coil. It dispenses with the timer and practically all of your present wiring, insuring a perfect timed spark and freedom from trouble.

The only satisfactory distributor system for the Ford magneto. Furnished complete to the smallest detail.

THE RHOADES BATTERY IGNITION SYSTEM

is intended for the class of Ford owners who prefer to ***dispense entirely with vibrators.*** This system operates entirely on battery, six dry cells supply ignition for from two to four thousand miles. ***We supply a handsome non-vibrating coil fitted with kick switch,*** also elevating gear bracket. Six years of hard service have proven it to be the best battery system obtainable for Ford cars.

PRICE $20.00

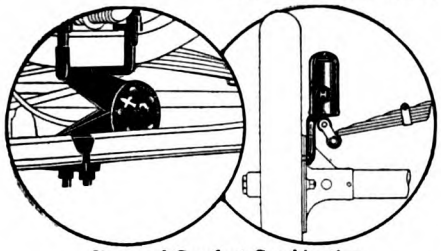
STANDARD Hartford EQUIPMENT FOR Ford CARS

LESS JOLT, LESS JAR, MORE COMFORT FOR FORD OWNERS



Here is a comfort combination scientifically correct and a pronounced success in practice—

FAMOUS *Hartford SHOCK ABSORBER
On the front of your Ford

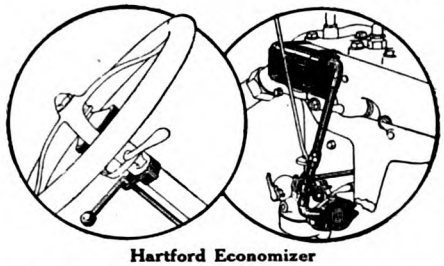
AND

FAMOUS Hartford CUSHION SPRING
On the rear of your Ford

The result of a special study of Ford requirements.

Hartford Comfort Combination

The Hartford Shock Absorber on the front of a Ford modifies and softens the spring action at this point, accelerated as it is on rough roadbed by the extra weight of engine. Two Hartford Cushion Springs on the rear, where there is less weight and less spring action, give the rear springs needed resiliency. Thus equipped, a Ford rides with solid comfort over all roads.



PRICE {ONE HARTFORD SHOCK ABSORBER / TWO HARTFORD CUSHION SPRINGS} **$12**

35% Less Gasoline and Much More Power

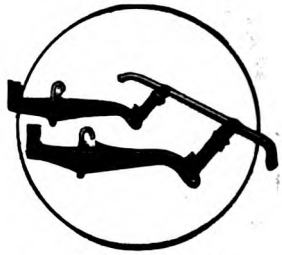
The engine of a Ford gets gasoline and air in perfect proportions when its engine is equipped with a

Hartford ECONOMIZER

PRICE, COMPLETE, $6.

Hartford Economizer

The air is warmed by a small air stove which receives its heat from the exhaust manifold. The result is that the engine, fed with an ideal mixture, is smoother-running and more powerful. All this is accomplished with an actual saving of 35% in the gasoline hitherto consumed. That's real economy.



PROTECTS WHILE ADDING A TOUCH OF REAL STYLE

A bumper is a necessity but it must be dependable. The

Hartford BUMPER

is, for it is shock-absorbing. It protects lamps, radiator and mud-guards from contact with the colliding body and at the same time takes the force out of the blow. This saves **all** your Ford from damage. Strong, sturdy, beautifying. Not an adaptation for Ford car, but designed especially for it.

PRICE, COMPLETE, $10

Hartford Bumper

Standard Hartford Equipment for Ford cars adds immensely to the pleasure of Ford ownership. You buy with this guarantee—Satisfaction or Money Back.

We can make any car fit to carry any load over any road with absolute comfort.

On the Cow—One
Off the Cow—Three

AFTER the hide becomes leather it is sliced into several sheets. But—there can be only *one* top, hair-side layer of genuine grain leather. The rest are merely splits, artificially coated and embossed to look like the real thing. These splits are sold as *genuine* leather, but they give neither the service nor wear of true hand or machine buffed leather. Thus we come to

DU PONT FABRIKOID
REG. U. S. PAT. OFF.

Rayntite Tops

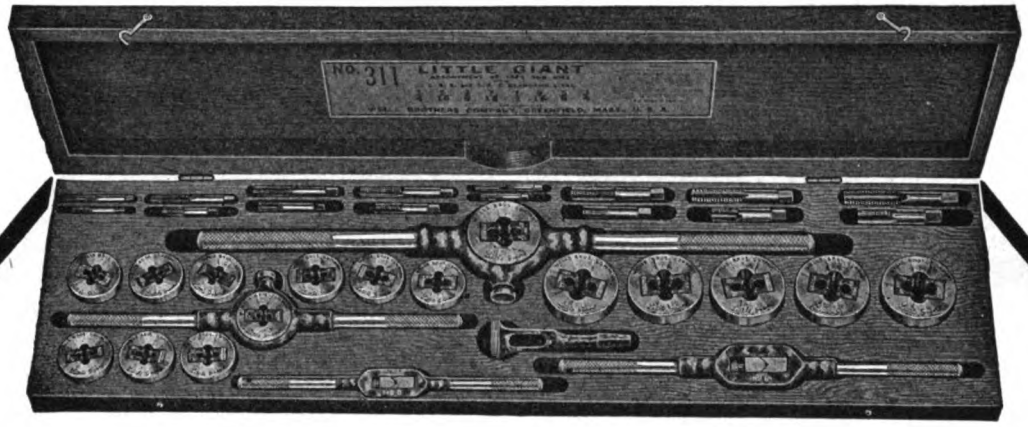
Rayntite Fabrikoid, the highest grade top material on the market, is proof against drizzles or cloud-bursts. Long and sincere tests at our experimental station have proved this. It is made in single or double texture, and both bear the Du Pont guarantee not to leak, peel, crack nor blister. Crown your car with Rayntite. Any top maker can build you a new top or re-cover your old one with Rayntite.

The Ideal Upholstery Material

Guaranteed Superior to Coated Splits

Fabrikoid looks like leather but it is not leather. It is made of a strongly woven cloth coated with a flexible, durable compound exactly duplicating the luxuriant feel and appearance of the finest plain and Spanish leather; but—it is far more lasting than coated splits.

It makes cushions and seats combining luxury and style, because it goes on smoothly—tufts beautifully, and is water, dust and grease proof. Furthermore, it is guaranteed for one year. And back of this guarantee stands the century-old Du Pont reputation for integrity of purpose, superiority of product and financial responsibility.



After two years of convincing success, Motor Quality Fabrikoid is being used on over a quarter million of this year's cars of various leading makes. Its merits have fully established its standardization. Be sure. Choose a "Fabrikoid" auto. Any automobile manufacturer can supply you.

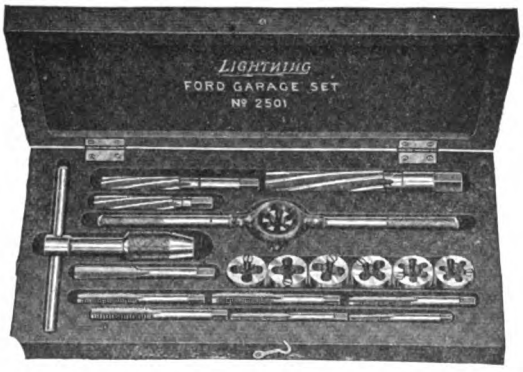
Little Giant AUTOMOBILE SCREW PLATES

GOOD WORK REQUIRES GOOD TOOLS

Now that the overhauling season is at full blast repairmen and garage owners need tools for cutting screw threads by hand and should have the best. Out of our large and varied list of assortments of taps and dies we want particularly to call your attention to the screw plates, one of which is illustrated above, called

Little Giant COMBINATION ASSORTMENTS (Containing both S. A. E. and United States Standard Threads.)



These assortments avoid the expense of buying a separate outfit for each thread standard and the expense of duplication of stocks and tap wrenches.

Little Giant DIES CUT EASIER **Little Giant DIES ARE MORE DURABLE**

Impossible for them to tilt or get out of alignment. Increasing the working strain only tightens the grip of the collect upon the working parts of the dies. Send for circular, "Tools for the Automobile." A postal brings it.

WELLS BROTHERS COMPANY DIVISION

LIGHTNING GARAGE REPAIR SET FOR FORD CARS

TAPS, DIES AND REAMERS—No. 2501

Designed especially for repairs on **Ford Cars, Model T.** A necessity for every garage and repair shop.

Contains:

Seven sizes taps and dies cutting
$1/4^{28}$, $5/16^{24}$, $3/8^{24}$, $13/32^{16}$, $7/16^{24}$, $7/16^{14}$, $1/2^{20}$.

Reamer for connecting rod arm bushing.
" " spindle " "
" " wrist pin " "

Stock and T tap wrench—all contained in neat hardwood case.

Write for catalog describing other screw plates for automobile repairs.

TEMCO Automobile and Garage Necessities

TEMCO Shock Absorber For FORD Cars

They take all the slight jars which your big springs would pass along to you.

They catch the first shock of all big jars and hand the load to the springs gradually.

They take the rebound from the springs gradually—and you are saved from all sudden or violent jars and jounces.

3 Big Features

Combined In No Other Ford Shock Absorber

1 Telescoping Dust Cap

The fender rods on Ford cars would ordinarily strike the top of a shock absorber as tall as the Temco. But Temcos **telescope** and "duck" the blow.

So we don't have to make them lean over to avoid the fender rod.

Temcos stand erect as sentries and add to the appearance of your car. They are absolutely vertical.

2 Longer Springs Stronger Springs

Even when telescoped, Temcos are as tall as others. When normal, they are the **tallest.** This is a big advantage.

It lets us use **longer** springs.

And we make them **stronger** and more **flexible** too. We use **two** Genuine, Crucible, **Vanadium,** Helical Steel Springs in each shock absorber.

They **couldn't** be longer — they **couldn't** be stronger.

3 Radius Links To Prevent side-Sway

Temco Shock Absorbers never lean one way or the other. They stand uncompromisingly erect—always absolutely vertical—giving full spring action.

Radius Links **hold** them straight.

This prevents that tiring side-sway.

And side-sway is the beginning of the dangerous skid.

By preventing side-sway, Temcos minimize skidding.

$15 Complete Set of 4

Unlimited Guarantee

Temco Shock Absorbers must fully, thoroughly and completely satisfy you in every way, or you may return them and get your money back.

To Dealers We were the first to make shock absorbers for Ford Cars and we've made and sold thousands more than anyone else. We are right behind them as we have been for years. We've a valuable reputation to defend. When you stock Temcos you stock the shock absorber which already stands highest in the confidence of most Ford owners and the one which will make a trade-boosting friend every time. Write for any information you desire.

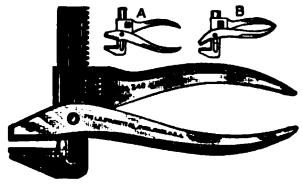
If You Own a Car You Should Own These Tools

BY INVITATION MEMBER OF

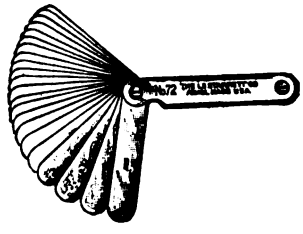
NEW YORK U.S.A.

Every man who owns a car knows the necessity for handy tools in the tool box when there is no garage nearby. For emergency repairs or for overhauling your car you will find need for all of these

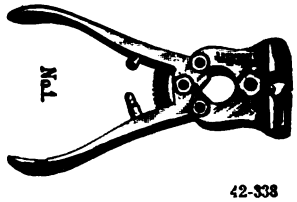
Starrett Tools



They are convenient and useful. The combination square may be used as a rule, square, or level. The calipers are used in taking sizes of any part. You often need a hack saw to cut some metal part or to fit a piece for temporary repairs.



The expansion pliers are the most useful pliers made. They give the plier action on large work far beyond the reach of ordinary pliers. Their grip is extremely powerful. The thickness gage or "feelers" are useful for setting sparking points and for determining thickness of shims for loose parts.



The cut nippers are quick cutters on wire and small stock.

Send for our 320-page catalog No. 20 D. C. showing complete list of tools and prices.

Starrett Tools are sold at all good hardware stores.

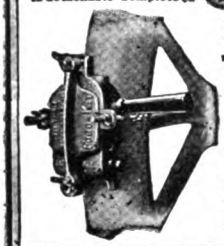
Stop the Hole—Save the Tire

Like a "stitch in time saves nine" so vulcanizing the small hole saves the blow-out later on.

These small holes when neglected expose the fabric. Sand blisters form. Water and moisture ooze through and rot the fabric. Then comes the blow-out—a big repair bill and usually a ruined tire. Stop this needless trouble and expense.

You can save your tires, save repair bills, increase your mileage and prevent tire trouble by vulcanizing the smal cuts and holes with a Shaler Vulcanizer You can keep your tires in perfect condition all the time.

SHALER Vulcanizers



Increase Your Mileage—Save Repair Bills—Prevent Roadside Delay

SHALER

Tube-Kit $2.00

Does away with temporary patches for repairing tubes. Can be carried in the tool box for roadside repairs or can be used indoors. Is free from soot and smoke and the fuel cannot spill and flare up Handle is detachable Complete $2

SHALER

Ford-Kit $2.75
For Ford Tubes and Casings

This model, designed especially to fit Ford tires, makes every practicable tube and casing repair. Safe, simple, clean—no exposed blaze

will repair any puncture, rip, cut, tear or hole in casing or tube in a few minutes and make the repair the strongest part of the tire.

The Shaler is simple and easy to use. Anyone who can drive a car can easily and quickly vulcanize any tire with a Shaler. It requires no watching or regulating. You do not have to fear overcuring or undercuring the rubber. The Shaler has an **automatic heat control** which provides the exact heat for perfect vulcanization—no more—no less. Shaler vulcanizers are standard. Their principle is correct.

We are the world's largest makers of vulcanizers and make a complete line for every need, in every type—Alcohol—Gasoline—Steam or Electric. We make small portable outfits for tourists—Tube Kit, $2.00, (for vulcanizing tubes), Ford-Kit, $2.75, (for Ford owners), Vul-Kit, $3.50, (To carry in tool box for roadside repairs to tubes and casings), Model D, $12.50, (Electric outfit for private garages) and Garage Outfit at $60.

Get This Book Free
"Care and Repair of Tires"

"Care and Repair of Tires" tells the proper inflation you should maintain in your tires according to weight, load and seasons. It describes fully how to protect the tires while car is idle in the garage—how to care for them in winter and extreme hot weather—how to avoid substances that rot the rubber and fabric. It gives splendid hints on the spare tire and its care—how to carry extra tubes. It is really a text book on the care of automobile tires. It also describes each Shaler Model in detail and explains how it operates.

To Dealers—Garages and Repair Shops

Garages can add $20 or more a day to their profits vulcanizing tires with Shaler Vulcanizers. Accessory dealers can greatly increase their sales and profits selling portable Shaler Vulcanizers to motorists. Every repair shop should have the Shaler Garage Outfit. Every accessory dealer should stock the tourist Shalers. Use the coupon today. Get our interesting proposition and read our free book "Common Sense About Tire Repairs" (for dealers only).

Carbon Trouble is a Piston Ring Trouble

IT'S not the fault of the oil at all—it's due to defective piston rings.

¶ All good lubricating oil must contain carbon, but carbonization only occurs when the oil is allowed to get where it has no business to be—in the combustion chamber. It's the duty of piston rings to keep it down in the crank-case where it rightfully belongs.

¶ Don't blame the oil. Put in

LEAK-PROOF

Piston Rings

MADE BY McQUADE-NORRIS MFG. CO.

and you'll reduce carbon trouble to a minimum. You'll get more power, too, for LEAK-PROOF Piston Rings are gas-tight as well as oil-tight—resulting in perfect compression, less friction loss and less motor wear. They will save both oil and fuel.

¶ Put a punch in your motor by installing LEAK-PROOF Piston Rings. They are perfect-fitting, equal-bearing, enduringly-elastic rings. They are made with mechanical exactness to overcome the inefficiency of other rings. Neither gas nor oil can get by them or through them.

In Use in Over 300,000 Motors

Send for FREE BOOK—

"To Have and to Hold Power." It explains the theory and function of piston rings and shows you why you should equip your engine with LEAK-PROOF Rings.

When leaving your car you simply take the key with you, which leaves the whistle open so that your engine cannot be started without the same blowing loud enough to be heard blocks away.

It is a whistle that will blow for you as long as your engine goes, with just a kick of your foot, thereby giving you the use of your hands and feet in case of accident.
It is a whistle that will prove it was blowing at time of accident, if necessary.
It is a whistle that will tell you if a cylinder is leaking or skipping on your engine.
It is a whistle that cleans itself. ***Write for prices and full particulars.***

ALFRED H. CLARK, 1307 HOWARD AVENUE BRIDGEPORT, CONN.

The Most Perfect Piston Rings Made

PERFECTION PISTON RINGS

They are made of soft, elastic steel in sections 1/16" wide and one section is required for each sixteenth in width of the groove. They give compression and power to your motor unequalled by any other rings. They present a barrier to the gas in the combustion chamber such as cannot be possible with a one piece ring.

This construction gives perfect compression, maximum power, minimum carbon, smaller oil consumption, lower gasoline bills, less smoke, and saving in repair bills. These rings are put on the pistons without being stretched, and this is impossible with one piece rings, which are always distorted when stretched over the pistons.

PERFECTION PISTON RINGS are made in all sizes and can be sold by dealers to great advantage. *Let us give you special quotations for your requirements.*

EVERY FORD NEEDS A WALDEN WORCESTER WRENCH

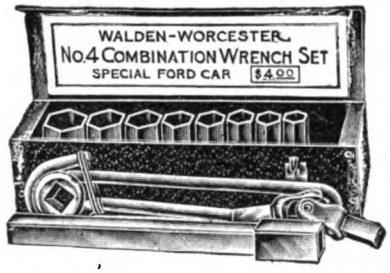
MR. FORD OWNER

Walden-Worcester wrenches for Ford cars have been built *specially* for use on the Ford. They are designed to meet the hardest service. Every wrench is *guaranteed*. Your money back, if it fails to do the work required. If your dealer tries to substitute and hand you a cheaper tool, demand the **Walden-Worcester**—(Look for the name on the tool and get your money's worth. Insist on a **Walden-Worcester.**

No. 1620—Triple Socket Wrench for Cylinder Head and Housing Bolts

The most useful single wrench for Ford cars. Cylinder head bolts, rear axle nuts and housing, water intake pipes and sundry other places. The offset gives necessary leverage for tightening or releasing bolts, the tee handle feature being wonderful for quick work.

PRICE **38c**

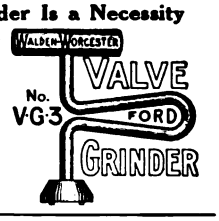


No. 4564—For Reverse and Brake Bands

The only wrench for use on brake and reverse bands, giving a full clearance around nuts. The peculiar shape of the handle allows full working space at all times. A Ford car is not complete without one of these wrenches.

PRICE **50c**

No. 4—The Set That Fits Every Bolt and Nut on Fords



A complete outfit that enables you to reach *every* nut and bolt on the Ford. It is the strongest, simplest, best constructed ratchet wrench set ever devised. Every part of this set is made for service and absolutely guaranteed against defects. With this outfit you are prepared for any emergency. Every Ford owner endorses it. It will pay you to invest in one of these sets today.

PRICE **$4.00**

A WALDEN Valve Grinder Is a Necessity

Consists of a special brace having a grip hold attachment that fits into the Ford engine valves. Will grind Ford valves better and in less time than any other valve grinder on the market. Made of Bessemer Steel Rod. You will like this little tool and will be glad to recommend it to your friends.

PRICE **30c**

ASK FOR OUR LATEST CATALOG

We have a money-making proposition in our new catalog that will be of extreme interest to you. It's something you have always needed. It will pay you to write. Just say, "Tell me about that 'box' you are giving Free."

MR. FORD DEALER

Walden-Worcester wrenches for Ford cars are *big sellers.* They are the most practical, most reliable tools that you can handle. Every Walden-Worcester specialty is backed by a *guarantee* that protects you and your customer. Why sell inferior, unreliable tools when you can sell the *best* at the same price? You will make *more* money in the long run by giving your customers **Walden-Worcester Wrenches.** Ask for our Wholesale Price List.

No. 5810—For the Connecting Rods

A tool of the greatest practicability and service, one that reaches any position without removing the motor from the car. Its peculiar shape affords splendid grip and powerful leverage. No Ford owner should be without one.

PRICE **35c**

No. 1824—Double Socket Wrench

A splendid double end wrench for removing main bearing and engine base bolts, etc. Sockets are of different size and are steel machined. They are case hardened and applied to the rod by our special process. Guaranteed not to twist or shear off.

PRICE **35c**

INLAND

1 PIECE PISTON RING

A marvel of simplicity and efficiency. Made of only one piece, it has all of the virtues of eccentric, concentric, and more than one piece construction, and none of their disadvantages.

A continuous ring cut spirally for half of its circumference, heat-treated, so that the free ends will hug tightly together. That's the construction—the result is :

An absolutely gas-tight ring that uncoils in expanding, insuring uniform pressure and perfect contact with the cylinder walls.

The strongest ring on the market, because it is made of one piece, and

1 The gap is less than 1/3 the width of the ring.

2 The free end is supported by the full depth (cross section) of the ring.

3 The friction surface of the free end is less than 1/3 its depth, making it relatively very strong.

4 It is easier to put on and will not break in handling.

The best ring on the market, at a better price. Absolutely guaranteed. Money refunded on any ring not giving satisfaction at the end of 90 days.

The Inland will be the biggest seller. Dealers and jobbers, write for interesting prices. Full description in booklet. Free.

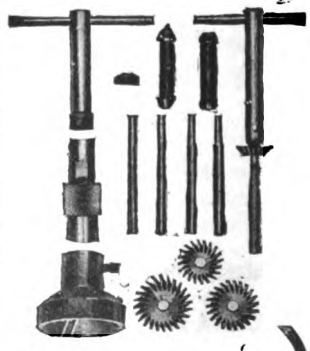
—crank shafts,
—cracked cylinders,
—rear axle housings,
—all automobile parts in brass, bronze, copper, aluminum,
—everything in metal.

Cuts
—axles,
—frames,
—rivet heads,
—any thickness of steel or wrought iron.

Removes Carbon
—from gas engine cylinders in a jiffy.



Welding Broken Torque Rod on Road

Every Garage Needs This Valve Reseater

Grinding valves and valve seats isn't the difficult, time consuming task it used to be. The old hand process of valve reseating was tedious, slow, and inaccurate. By doing the work with the modern, efficient, time-saving **FOSNACHT VALVE RESEATER** you get absolute accuracy—cleanliness—and use but a quarter of the time formerly required. An inexperienced man can do perfect work with this remarkable appliance. There's no emery—no dirt—no tearing apart of motor—where the

FOSNACHT VALVE RESEATER

is used. Every garage needs the **FOSNACHT.** Its speed and reliability brings increased repair business. The price of $25.00, with a 5% cash discount, is an actual investment, with liberal profits from valve grinding work the certain returns. Will pay for itself in a short time. Many in successful use.

You ought to have our book telling all about this machine. Your name and address on a post card, with a request for the **FOSNACHT** book, will bring it by the next mail.

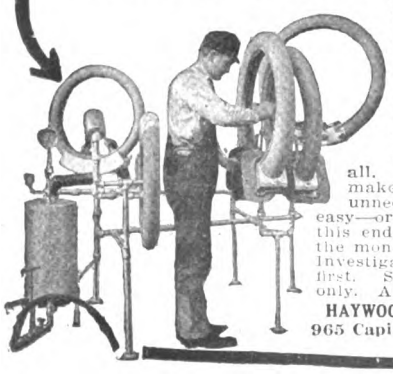
Add $250.00 A MONTH EXTRA To Your Business



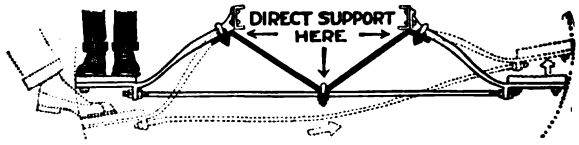
REPAIR AUTOMOBILE TIRES

Sounds like a whole lot of money to clear extra every month. Seems almost impossible, but that is what hundreds of men are doing who have added a Tire Repair Department to their business. **The investment is small, the profit large** and **returns quick and all cash,** besides the demand for tire repairing and retreading is constantly growing. Your garage is by no means complete, your business is not as profitable as it can be until you get in on the Tire Repairing and Vulcanizing end.

THE HAYWOOD TIRE REPAIR EQUIPMENT

Answers all the requirements to successfully handle this end of the business. With it and a little business judgment, success is certain. Every year adds thousands of new auto owners. They are looking more and more to economical tire service. The day of discarded tires is over, the Haywood Equipment makes this possible.

HERE IS YOUR OPPORTUNITY



Either as a side line to your present automobile business or as a business by itself, the Haywood Equipment will make money for you. **Tires go wrong all the time.** You know that. Keep them in tune. Give your customers complete service—repair their tires and all. This builds business and makes you rich. Experience unnecessary. You can learn easy—or teach a boy to handle this end. Be the boss and make the money. Learn the details now. Investigate. Act quick. Be the first. Send name and address only. A postal will do.

Running Board Braces.

Make Your Ford as Quiet as an Electric and as STRONG as a Truck.

DOTTED LINE shows the teeter and buckle as you step on your car now.
SOLID LINE shows how rigid *CASEY* braces are guaranteed to make it.

Why not stop that rocking and teetering in your automobile? Every time you or one of your passengers step into or out of your car (as illustrated by the dotted lines above) your truss rods, frame and fenders are strained into most strenuous contortions and then quickly released back into normal position again.

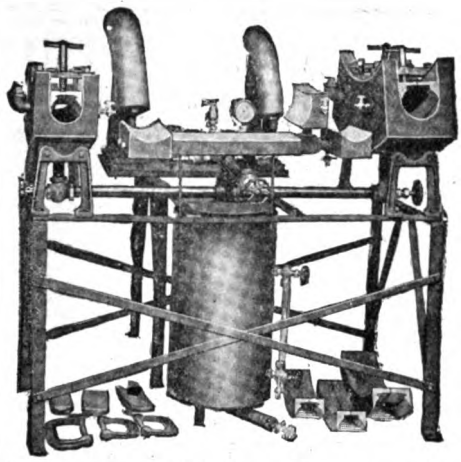
Is it, therefore, any wonder the mud guards become loosened at their fastenings and rattle or the truss rods snap off at the threaded ends?

Two dollars invested in a pair of *Casey* Braces will positively insure your Car against this abuse during its entire life. Will make your Running Boards STRONG and QUIET.

You can safely carry battery and tool boxes, entire camping or touring outfits or other loads on your running boards and there will be no strain or pull on your rods or fenders to make them LOOSE and NOISY.

The three-point suspension as used in bridge building and other metal construction, is an accepted standard, because it is scientifically right. Your Automobile will be rigid because the strain is equally distributed between the three points of support as indicated by the three arrows in the illustration, and jumping on the step with both feet cannot strain your Chassis in the least.

You can easily attach these braces in a few minutes yourself, and they will positively do wonders for your car. No drilling or fitting necessary. All you need is a wrench. Shipping weight, 4 pounds.



***Casey* Running Board Braces,** per pair complete..... **$2.**

All Cash Orders received for the next 30 days will be sent prepaid.

Your Best Interests Demand Micro Piston Rings

Leaky old style rings are a prolific source of wasted gas and oil, and by inviting excessive smoke, soot and overheating are often directly responsible for lost power, heavy carbon deposit and dirty and warped valves.

Micro pressure-tight rings, by keeping gas and oil each on the respective sides where they do the most good, keep the motor clean and snappy, always able to pull heavier loads and get up hills with less gear shifting.

Made from flexible resilient metal that **never breaks in fitting** and remains tight with the cylinder wall when old as well as while new.

Write for our proposition and booklet, "How Micro Rings Improve Efficiency."

The New Schrader Quick-Acting Dust-Cap

The operation of testing the air-pressure in tires having been found on occasion difficult and irksome by reason of the jamming together of the valve stem and dust cap, the firm of A. SCHRADER'S SON, Inc., have designed and placed on the market a new "Quick-Acting" Dust Cap which can be removed from the valve stem by a simple quarter turn.

The new SCHRADER "Quick-Acting" Dust Cap eliminates the work of screwing the cap down the entire length of the valve stem to the felloe of the wheel. All that is necessary is to slip the cap over the valve and turn it one-quarter turn. This locks it securely to the valve stem. To unlock, simply give one-quarter turn in the opposite direction.

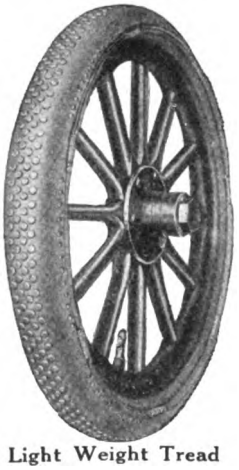
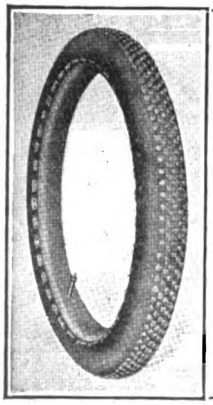
TROUBLE SAVERS FOR MOTORISTS

Woodworth Trouble-Proof Tires



Woodworth Trouble-Proof Tires are guaranteed against punctures for 5000 miles. They are also guaranteed to outwear any other make of tire on the market and if used on one side of the machine against any other make on the other side and they do not wear longer except when destroyed by accident, we will refund 2½% of the purchase price for every one hundred miles they fall short of the mileage given by the other make.

Woodworth Trouble-Proof Tires have a puncture-proof strip of chrome tanned leather in them which prevents punctures without stiffening the tire and without causing it to ride hard or overheat. The rubber and fabric used in these is the very best that can be obtained at any price. These tires will not only give you freedom from tire troubles but they will cost less per mile to run than any other tires you can obtain.



Woodworth Treads

Woodworth Treads are made in two weights:—The Heavy Weight Treads which are made with extra hard studs on the middle portion and are guaranteed for 5000 miles. The Light Weight Treads which are made with softer studs, which weigh only about half as much as the ordinary treads, will average 2000 to 3000 miles.

Woodworth Treads are puncture-proof. They protect the tires from all outside injury and road wear and do away with the bother of chains for wet and slippery roads. They are especially valuable for use on bad roads and for running on any roads in fall, winter and spring.

Light Weight Tread

Woodworth Tire Restorers

Woodworth Tire Restorers are especially intended for use over old tires. They fasten to the rim so that they strengthen the tire and prevent blow-outs; are also puncture-proof and an excellent anti-skid and traction device. Cost only about half as much as the ordinary tires.

Easyon Chains

Easyon Tire Chains are individual chains fastened to the spokes. They can be applied in an instant even when stuck in the mud. If you carry a set of EASYON CHAINS, you can feel you will not get stuck in any place where the car has power enough to drive it.

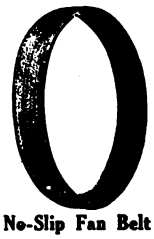
Price $3.20 per set for chains to fit tires up to and including 4 inches.

$4.00 per set for tires larger than 4 inches.

Sent postpaid to any part of the U. S. on receipt of price.

Spring Oiler Strap

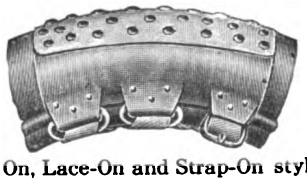
Spring Oiler Strap



Spring Oiler Straps buckle around the spring. They have a ply of wicking on the inside which can be kept saturated with oil by occasionally oiling through a hole on the top which is covered with a leather flap. Fit all makes of cars and are very easy to put on and very easy to oil after they are in place. They are unbreakable and the most economical as well as the most satisfactory spring oiler on the market.

Price 25 cents each; $1.00 for a full set for a Ford.

No-Slip, No-Stretch Ford Fan Belt



No-Slip, No-Stretch Ford Fan Belts are made of a strong webbing having a leather covering next to the pulleys. The leather is especially treated so that it never slips; is not affected by oil, water or heat. The real no-trouble fan belt.

Price 40 cents each, sent postpaid to any address.

No-Slip Fan Belt

Woodworth Tire Boots and Inner Sleeves

Woodworth Tire Boots and Inner Sleeves for weak and blown-out tires. They are handy for emergency use or to enable one to wear out his old tires without vulcanizing. Made in Hook-On, Lace-On and Strap-On styles at all prices from 50c up.

Send for our free booklet entitled TROUBLE SAVERS FOR TIRE USERS. It will give you information that will be worth many dollars to you.

DRY BATTERIES.

Their Evolution and How They Can Be Made to Give Good Service.

BY SYDNEY F. WALKER, M. E.

No. 2.

As originally designed, the Le Clanché cell was not intended to furnish currents continuously; it was intended to use intermittently for electric bells of private houses, the electric signals of mines, and later on, of telephones. The same principles that had ruled in the Daniell battery ruled also in the Le Clanché, though they were applied in quite a different manner. It is the hydrogen gas that is given off at the carbon or copper plate of each cell that causes the trouble. If it is allowed to accumulate it sets up a counter electromotive force, a counter pressure which tends to reduce the pressure available from the cell. It will be remembered that every pair of metals, when immersed in a liquid, give rise to an electric pressure between them. In this matter hydrogen gas behaves just as a metal, but the above statement may also be extended by saying that any two dissimilar substances which are together in presence of a liquid will set up an electrical pressure. When hydrogen gas comes away at the carbon or copper plate a galvanic couple is set up consisting of the carbon and hydrogen gas, with the liquid that is surrounding the carbon or copper plate. If the hydrogen gas is immediately got rid of the cell will go on working. In the gravity Daniell battery described above the constancy of the pressure is maintained by reducing the current to such a figure that the sulphate of copper present in the cell can easily deal with the hydrogen as it is given off. If such a battery is worked beyond a certain rate it quickly begins to drop its pressure because the hydrogen gas cannot be neutralized as quickly as it is given off. It will be seen later how important this is in the matter of the dry cell.

In the Le Clanché battery a property possessed by oxide of manganese is employed to perform the same work as that performed by the sulphate of copper. The hydrogen gas given off in a battery is in a very powerful state, and oxide of manganese very readily gives up a portion of its oxygen, the salt being reduced to a lower oxide. The oxygen so given up unites with the hydrogen, one atom of oxygen combining with two atoms of hydrogen to form water, which of course is merely added to the solution in the battery. The oxide of manganese in the wet Le Clanché battery, which is still upon the market, is contained inside a cylindrical porous cell, as shown in Fig. 7. A carbon plate stands in the middle of the porous cell, and the space around it is filled with a mixture of oxide of manganese and carbon, both crushed to about the size of a pea. It is of importance that there shall be no dust present in the cell. The top of the porous cell is closed by a pitch seal, a glass tube being inserted in the pitch to allow of the escape of gas.

A zinc rod was employed in the early forms of Le Clanché cell and is to-day employed usually in the wet cells. It is shown in Fig. 8. The zinc rod stands in a solution of sal ammoniac, chloride of ammonium. Ammonium, it will be remembered, is a hypothetical

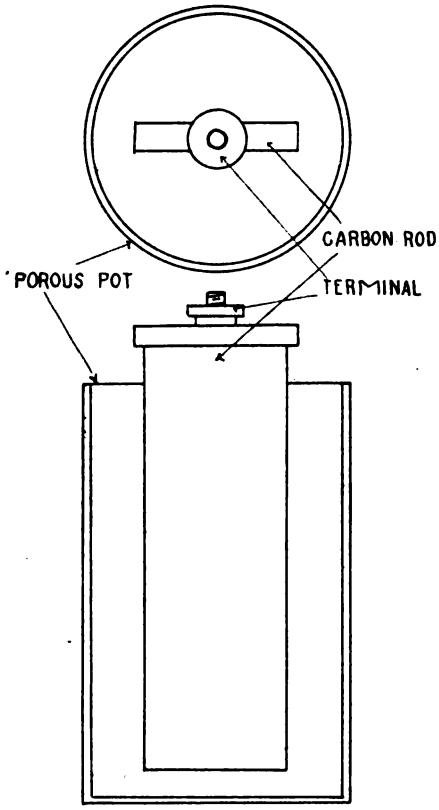

Fig. 7—Section and plan of the filled porous cells of a Le Clanché battery, showing the carbon plate and the porous cell. The crushed oxide of manganese and carbon referred to in the text are filled in round the carbon plate.

metal; it does not exist. But there are a number of salts formed with the hypothetical metal in the same manner as with zinc, copper, etc. There is for instance sulphate of ammonia, which has at present a large sale for agricultural purposes, and which is made largely in gas works and as a by-product from coke ovens. Chloride of ammonium is a white salt, sometimes placed on the market in large blocks, but more usually in a crushed form, as it more easily dissolves in water in that condition.

When the cell is working zinc combines with oxygen from the water, and with chlorine from the ammonium chloride, hydrogen being liberated by decomposition. The hydrogen appears at the carbon plate, and there it seizes upon the oxygen set free by the oxide of manganese, forming water as already explained. There are several points in connection with the wet Le Clanché cell, that bear very strongly upon the working of the dry cell, and they will probably be more easily understood if explained in

Digitized by Google

connection with the wet cell. The working of the cell depends upon several important provisions. In the first place, like the Daniell cell if the current taken from the cell is beyond a certain figure, if it comes away at more than a certain rate, the oxide of manganese is not able to apply oxygen sufficiently fast and the pressure furnished by the cell is then quickly lowered.

But there is a very important saving clause. Any size of cell may be worked beyond its proper current, supposing that the current was taken from the cell continuously, if there are periods of rest between the times when the current is taken. Thus, in the case of mining signals, for instance, though the current

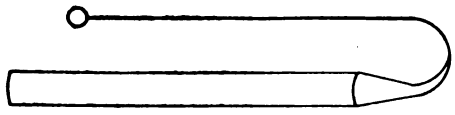

Fig. 8—Zinc rod with copper connecting wire for Le Clanché cell.

required to strike the bells is fairly large, at each signal, the battery has a rest during the time the cage is being hauled to the surface and the oxide of manganese is able to recover itself. The process of recovery has not been thoroughly investigated but it is probable that the surplus hydrogen gas and ammonia gas which is also given off at the carbon plate are able to escape during the period of rest so that the cell again becomes normal, providing the period of rest is sufficiently long. It should be mentioned that the ammonia that the hypothetical metal ammonium splits up in the process of working the battery into ammonia and hydrogen gas, no attempt is made in the Le Clanché cell to neutralize the ammonia gas, it is allowed to escape through the glass vent mentioned above. The quantity of ammonia gas given off apparently is not sufficient to interfere with the working of the battery, providing that the hydrogen is neutralized and also providing that the rate at which the battery is worked, the strength of the current taken from it does not exceed a certain figure. There are, however, certain secondary actions in which the ammonia gas plays an important part, which will be dealt with later. If a Le Clanché battery, and all dry cells, it will be remembered, are Le Clanché cells, is worked at a very high rate, at a higher rate than it was made for, there will be a strong smell of ammonia gas. Everyone knows the smell, and when attending to a battery of this type it is a sure sign that it has been overworked if there is a smell of ammonia gas. Incidentally the writer might mention a cell which he introduced a good many years ago, upon the same lines as the Le Clanché, in which sulphur, crushed to about the size of a pea, was employed, instead of oxide of manganese. The action in that case was the same in the zinc cell but in the carbon cell the hydrogen gas combined with the sulphur forming sulphuretted hydrogen gas, and the ammonia gas came away freely. The great objection to this cell was the very unpleasant smell produced by the sulphuretted hydrogen. Some cells that were tested by a divisional superintendent of the British Post Office, during the time the writer was endeavoring to put it upon the market, revealed this defect in a very striking manner. The battery was left to work a buzzer the whole night the whole apparatus being in the divisional superintendent's office. When the latter arrived in the morning the sulphuretted hydrogen gas was so very much in evidence he could not enter the office until the windows had been opened. The test which the post office man put the battery to was one which that size of battery was not intended to stand, but the result illustrates very forcibly what happens when a battery of this kind is worked at too high a rate. Sulphuretted hydrogen would be formed in the working of the battery under every condition, but when the cells were only furnishing the current for which they were made the gas would be absorbed by the porous carbon contained in the porous cell, and would work back into the liquid, or come away in such small quantities, through the vent tube, as to be quite inappreciable.

(To be continued.)

CARBON IN CYLINDERS.

How to Burn it Out Safely by the Use of Oxygen Gas.

BY M. KEITH DUNHAM.

Burning the carbon out of cylinders by the use of oxygen gas is a system praised by one, condemned by the other. Because it is a chemical, rather than a mechanical process, the mechanic may wholly misunderstand the use of the simple apparatus required, he fails to remove the carbon, and the conclusion immediately drawn is that the system is no good, when as a matter of fact, the process, with good oxygen and correctly done, will destroy the carbon.

Carbon is caused by imperfect combustion. It is present in both the oil and gasoline and is deposited

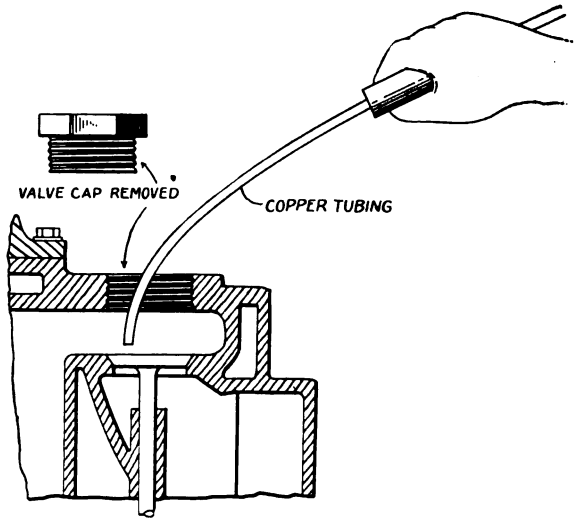

Fig. 1.

on the top of the piston and cylinder head and around the valves solely because the air admitted through the carburetor is insufficient to completely burn the fuel present, which may be some gasoline and some oil. The mechanic usually figures that carbon is caused by "too much oil," but inasmuch as oil will be completely consumed if there is sufficient air, the better explanation is that there has been too little air. Now air consists of practically two elements, 1-5th oxygen and 4-5ths nitrogen and it is the oxygen which supports combustion—that is, which is necessary to burn anything. The nitrogen acts as a dilutent only and its presence always acts as a check—in other words pure oxygen will burn any combustible very quickly and air, being diluted with 4-5th nitrogen, will burn it considerably slower.

Carbon is one of the best combustibles there is

Digitized by Google

and with oxygen to feed it, or support combustion, it will burn completely away in the form of a gas, leaving no deposit. The mechanic is undoubtedly familiar with the usual directions sent out with apparatus to shut off the gasoline with the motor running and to have the piston at the top with the valves closed and to then remove the valve caps, light the carbon with a match or taper and the work is done. These directions are all right up to the removal of the valve caps.

Note Figure 1, showing the copper tube inserted through the valve cap opening. The oxygen being under pressure, acts as an injector and sucks in air, the inevitable result being that combustion is retarded or stopped before the carbon is completely

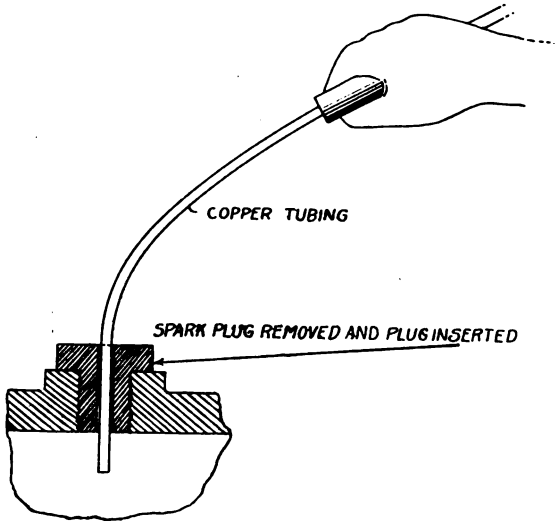

Fig. 2.

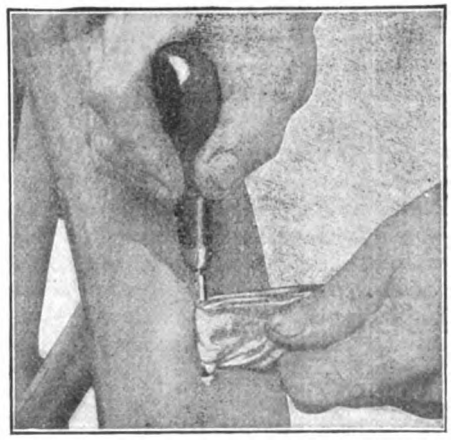
burned, because the air acts as a check. To prove better the dilutent effect of the air, take the valve cap and try to burn the carbon on it, while it is lying on the floor. The carbon stops burning almost immediately after it is lighted. Put the valve cap in a deep can, where the air can be more or less driven out by the force of the oxygen and the carbon on the valve cap burns quite freely—not completely, however, since the air can still get to it and dilute the oxygen. Then if the copper tube, carrying the oxygen, can be put into the cylinder with as little air space around it as possible, the results are going to be a lot better, since carbon must burn in an atmosphere of oxygen.

In Figure 2 is shown a screw machine part fitting over the copper tubing loosely and threaded to fit the spark plug opening. After the carbon is lighted, slip this part down the tube and thread it in one or two turns, the idea being of course to keep the air from being sucked in to the cylinder. There must be some escape for the burned gases, however, and if the cylinder has no pet cock to leave open, this screw machine part must fit loosely enough to allow these gases to come away. Carbon may be deposited in sections—that is the top of the piston completely covered and very little on the valves and there might not be enough to burn from one to the other. This can be more or less determined by the appearance of the spark plug. If very dry, squirt about a teaspoonful of oil, kerosene or alcohol in the form of a spray (a cleaning gun will do nicely), into the cylinder to assist the burning. If the spark plug is oily, however, this procedure is wholly unnecessary.

The pressure at which the gas must be used depends of course upon the size of the hole in the copper tubing. This hole should be about ⅛" and the pressure used about five pounds. The tubing is soft copper and should be kept moving around in the compression head to come somewhere near the carbon. Actual contact with the carbon by this tube is not necessary. Keep the pressure down. A high pressure means a rapid burning and is very likely to cause too much heat and consequent damage to the valves or piston. With a low pressure, there isn't the slightest danger of damaging the cylinder.



The writer believes some of these ideas are new, he is well aware that they are directly contrary to those advanced by some manufacturers of apparatus but a trial of them calls for no new investment and may place the ill-advised user of a carbon burning outfit on the right road.

TIRE REPAIRS.

Simple Directions for Roadside and Garage Vulcanizing by an Expert.

From C. F. Adamson, Ohio.—When the sudden bumping along the road announces to the alert driver that one of his tires has "gone flat" he immediately throws out the clutch and applies the brakes. He knows that fifty yards of travel on a deflated tire may mean the end of the career of both the shoe and tube, on account of the deadly rim-cutting. This stopping of the car immediately is really the first step in the work of repair. Every foot of unnecessary travel of the deflated tire means just that much more terrific strain and distortion on the tire, and a serious increase of the damage already done.

When tire casings are in good condition, the chances of a blow-out are much smaller than when they are old, and when the flat tire occurs it will

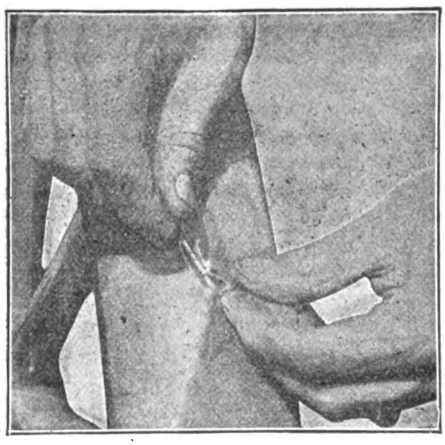
Cleaning Out a Cut With Screwdriver and Rag, Using Gasoline.

probably be in the nature of a puncture. Should there be no extra tubes along, the problem will be one of making a roadside tube repair.

The tube is removed from the tire, and the location of the leak is found. This will be possible by pumping some air into the tube, and either finding the leak by listening for hiss of the escaping air, or if it is very small, by dipping the tube in water, and watching for the bubbles at the point where the air is finding its way through.

When the leak is found, the remaining air should be removed from the tube. If it is a very small leak, the valve will have to be screwed out by inverting

Digitized by Google



the valve cap, and using it as a screwdriver, or if it is a large leak, the air can be squeezed through the hole. The tube is exhausted of air by rolling it up towards the opening used for the passage of the air, whether it be the valve or the leak itself. After the air is entirely exhausted spread the tube out flat with the leak up.

There are two methods of repairing an inner-tube. Either cement or no-cement patches may be used, or a vulcanized repair may be made by using a small portable vulcanizer. In making repairs with patches, the cement patches are harder to put on, but give better results than the so-called no-cement patches. The tube is prepared in the same way with either patch. With a small piece of emery, or sand paper, the tube is roughened around the cut, and then it is thoroughly cleaned with gasoline. The cement patch is prepared in the same way, first being rubbed with emery, and then cleaned with gasoline. An application of rubber cement is made to the tube and patch, and allowed to dry. Another coating of cement is added to the part to be mended and the patch, and when thoroughly dry a third coating is put on, and when nearly dry, the patch is pressed firmly on the tube, which will be very sticky.

The tube should not be used for about ten or fifteen minutes after the patch has been put on, and during this time a weight should be placed on the patch to hold it firmly in place.

With no-cement patches, the method of procedure is the same, except instead of applying cement to the patch, the tube is cleaned with gasoline, and the especially perpared patch is dipped in gasoline, and applied to the cut.

There are now on the market, vulcanizers which are so small that many car owners carry them on the road and make their repair permanent instead of using the always uncertain patch, which may last only a short time. These portable vulcanizers are

Filling the Cut with Repair Gum.

very easily operated, the exact method depending upon the type that is used, whether gasoline, steam or electric. The two latter types are particularly adapted for garage use, while the former is the type that is carried on the road.

When using one of these vulcanizers, the tube is prepared the same as if cement patches, referred to above, are used, except that vulcanizing rubber is used instead of the cement patches. It requires but fifteen minutes to vulcanize a tube. When the tube has been cleaned, some repair gum, which is supplied with the vulcanizer, is cut to a size to fit the hole in the tube. After the hole has been carefully fitted, a large piece of repair gum is cut to fit over the hole at least one-half inch all round its circumference. The larger piece of rubber is laid over the smaller piece, which has been placed in the hole tube, and the vulcanizer clamped down upon it. The tube is then ready to have the heat applied.

The method of doing this will depend upon the type of vulcanizer that is being used. With the gasoline type referred to a small amount of gasoline is placed in the receptacle and ignited. This will be consumed in from 10 to 15 minutes. After the vul-

Cutting Away the Excess Material After Filling a Cut.

canizing process is completed, the vulcanizer is removed and talc dusted over the point at which the repair was made. It can then be placed in the casings and used.

Long tears and large blowouts in tubes should always be repaired by vulcanizing. If they are very large, it is customary to cut out a section of the tube and put in a new piece. This new piece may be cut from old tubes, and it is good policy, for this reason, to save old tubes for a time when it is necessary to do some work of this nature.

"A Stitch in Time," Etc.

An hour spent in the garage, saves three on the road. An evening spent on the tire when the car is in the garage, will save many dollars during the season, and will save many an unpleasant experience on the road. The first work to be done is the permanent repair of the tubes which have been punctured or hastily patched. Slow leaks should also be located and vulcanized. This is the tube work.

On the shoes, the vulcanizing of cuts and tears and the curing of bruises will be cases to diagnose and heal. Repairing tubes in the garage will be the same as on the road, except that the repair should in every case be vulcanized. There are many owners of cars who rely on the cement or no-cement patch in making these repairs, but they are, without exception, the ones that will be found under the blistering sun, on the road, changing tires. A small vulcanizer can be bought for two or three dollars for use on the road and in the garage, and will have more than paid for itself after a season's use. Tire casings, or shoes, perish in two ways:

First—By the wearing away of the surface until the fabric is worn through.

Second—Through cuts, bruises and breakdown, due to underinflation or other abuses.

The object of the car owner is to have his tire

Digitized by Google

wear out in the first mentioned way. The second is poor economy. The first step in maintaining the health of a tire until it dies a natural death is the mending of the small cuts as fast as they appear. This is the biggest tire economy that can be accomplished by the owner, and it actually means dollars in his pockets at the end of the season.

It takes less than 15 minutes to prepare and vulcanize the average cut, and it is perfectly possible for an occasional 15 minutes to add 2,000 miles to the life of a tire. Tire cost on the car is generally three to four cents a mile. In other words you are earning $80 in this 15 minutes' time! The reason that the use of the vulcanizer is so important is perfectly familiar to anyone who has had experience with tires. It is the source of the greatest wonder to tire repairers themselves that people do not seem to realize the amount of money that is lost each year for failure to keep water out of the cuts in tires. The water goes into the fabric and ruins it in a remarkably short time. Sand works its way in and in a short time forms the much dreaded sand blister below the tread. When the tire is badly gone, the owner commences to think of having a section put in, that is having the bad part of the tire come out and a new piece put in. This is expensive, and it is always doubtful whether a tire repaired in this way will last long.

A small vulcanizer will do wonders with minor cuts. It does the work better than it can be done with plastic material, because it closes the hole or seals the hole, instead of merely filling it. Plastic material is gouged out after a time, or it deteriorates, while the vulcanized cut leaves the rubber in about the same condition as before it was cut, if the

Cleaning the Shoe With Gasoline and Cloth.

work is done correctly. The method of procedure is as follows:

Jack up the wheel with the tire inflated. Sit on a stool in front of the tire with the light coming over your shoulder, and have within reach the following: Thin bladed pocket knife; small screwdriver; small bottle of gasoline; roll of repair gum; small pair of scissors; some waste and soft cloth.

Revolve the wheel slowly, the top coming toward you, closely examine the surface of the tire for cuts. If the tire is dirty, wash the surface with soap and water, and dry it off with a piece of dry waste. When you come to a mark which has the appearance of being a cut, take the knife and carefully probe it. Very often you will find beneath the surface of the tire a small piece of glass, a piece of metal, or a sharp stone. Remove the offending article and scrape around the cut until there is clean rubber or fabric throughout the entire injury. This will give a good surface for the repair gum to take hold. After the roughening process is completed, a piece of raw rubber, which comes with the vulcanizer, or which can be secured from any auto supply dealer,

Gasoline Vulcanizer Applied to Inflated Tire.

is fitted into the cut. If it is a long cut that has taken off a considerable portion of the tread, a piece of repair gum is cut to the same shape as the piece torn off, or, if it is a cut merely to be filled, a small piece of repair gum is inserted in the cut. In the case of a cut or tear in the tread, the rubber is cut away from the damage portion in a rectangular shape, and a new piece of rubber is cut approximately to size and then pressed into place. The excess rubber is then cut away. If the cut is deep, two, and sometimes three, layers of rubber must be placed on top of the other, to bring the rubber up to the level of the surrounding tread.

The vulcanizer is applied to the damaged spot by means of clamps. On a very shallow cut, the vulcanization can be accomplished as quickly as 10 minutes. On deeper cuts, where there are two or three layers of rubber to penetrate, it will take about 15 minutes. The average time required for vulcanizing a cut will be from 12 to 15 minutes, from the time the vulcanizer is ignited to the time of removing it from the tire, when a vulcanizer of gasoline type is being used.

For the owner who does not care to do his own vulcanizing, it will be cheaper in the end for him to have small vulcanizing jobs done as they present themselves, rather than wait for the shoe to blow-out before anything is done toward the sealing of the cuts. If the cuts are allowed to go too far, it will mean that the shoe will either have to be replaced at the price of a new one, or an extensive repair will have to be made, with the usual doubtful results as regards economy.

"Under deflation and overloading are first cousins." The effect on the tire are similar, but the cure for the trouble is a higher pressure in the first case, and oversize tires in the second. It is not feasible to attempt to meet an overload by increasing the pressure in the tire. An overload for a given size tire can soon be met by putting on a larger size. Proper inflation is necessary at all times, but the user of the car must know that the

Digitized by Google

tires are capable of economically handling the load placed upon them in regular service. The tire manufactureers agree very closely on the amount of weight to be put on each size tire. They are also practically agreed on the inflation pressure, and a study of the tables published by them will show the proper inflation for any given size tire.

It is well recognized that an ounce of prevention is worth a pound of cure. Whether it be vulcanized cure or otherwise, it may be well to mention a few points of material benefit in lengthening life of a shoe: Keep spare tire protected from direct action of the sun. Heat and light deteriorate rubber rapidly, therefore, keep tires in a cool, dark place. Do not run along in ruts, car tracks, against curbs, or cross intersected pieces of car track. Apply the brakes as easily as possible, start gradually, run at moderate speed on hot days, turn corners slowly, and always keep the eye open for broken bottles, or any other tire destroying objects along the road. Either in a public or private garage, insist upon having the floor upon which your car is standing free from grease or oil.

Best for Carbonized Cylinders.

The method of cleaning cylinders by oxy-acetylene flames is gaining headway all over the country and there is no objection to it. Its temperature is less than that of the combustion of the gasoline in the operating motor and by the use of the flame, scraping by hand is done away with, which not infrequently caused the surfaces to be scratched. The work is quickly done by any expert garage man and does not call for removing cylinders or cylinder heads.

HELPFUL KINKS.

Simple Methods of Doing Certain Repairs Easily and at Little Cost.

From J. N. Bagley, Nebraska.—Hardly a day passes but some simple way may be found to do a hard thing, and if we make notes of it they will prove of value at some future time. To make a good repairman one must have inventive ideas and be a jack-at-all-trades, so to speak. For a good many years the writer was engaged in the gunsmithing business and it seemed that every little device that needed repairing was brought to him. Just why this was so I could not understand, but they were always turned out in working condition, and they came as long as I continued in the business.

When one sets out to do the repairing of all the little things that come to the shop he must be a handy man in order to handle it. The successful man in this line is the man who can figure out the how and why and get the parts to working in harmony. Many times one cannot take the time to order repairs from the factory and must make the little parts needed, such as springs, nuts, bolts, etc.

There are a number of parts about machines that are put together with hot rivets and to do this well is no easy job. A hot rivet will not work loose as a rivet placed cold, therefore it is much more satisfactory in many places. Take the auto frame, for instance. If these frames are bolted together they would shake apart in a very short time, and not stand the strain they are subjected to. To do a job of hot riveting we should have a tool shown at A, in Fig. 1. This tool is made from steel and the end drawn down and sunk as shown in section on the end at B. This permits of a head being formed on both sides of the rivet, and if the work is done well it will be hard to tell which side was the original head of the rivet.

At C we have two plates to be put together with hot rivets. At D the rivet has just been placed at almost a white heat and the tool, A, placed in position. Now, by striking A with a heavy hammer the rivet takes the position as shown at E, and also spreads out in the hole until it fits perfectly in the hole of the plates, C. Now by a few quick hard blows on the tool, A, the rivet assumes the shape shown at F, making both sides look the same. The rivet should be long enough to make a neat round head and should not be so long that the rivet would bend instead of forming into a perfect head.

Another very annoying thing is a nut that is con-

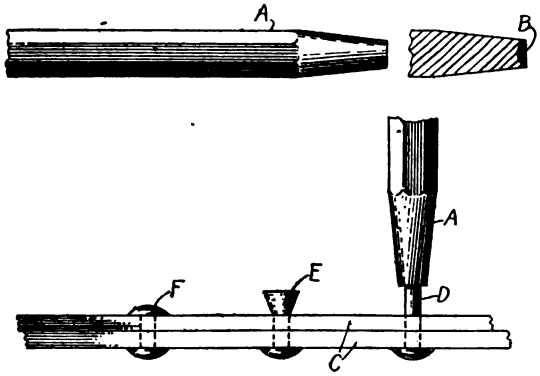


Fig. 1.

tinually working loose and playing havoc with some delicate adjustment that takes much time to remedy. There are many locking nut devices on the market and some of them are very efficient, but these are not always at hand and some other means must be used to bring about the results. A kink that I have found to be very successful is shown in Fig. 2. At A we have a nut which works loose quite easily. To prevent this we saw into the nut about half way through as shown at B. Now we place the nut and make the desired adjustment and take the punch and set it on the nut as shown at C, and strike the punch a sharp blow. This closes the top half and

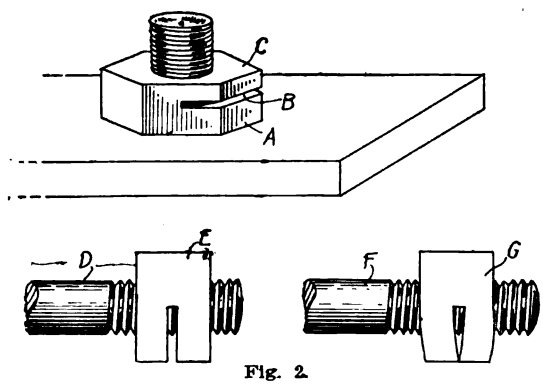

Fig. 2.

causes the threads to bind sufficiently to prevent the nut working loose. At D we have the nut in position on the bolt, but the nut, E, is not closed. At bolt, F, we have the nut, G, closed, and note the side of it as it locks the threads, so to speak. This does not prevent the nut being removed at will. In case the nut is removed it should be locked again when being replaced as already described. I have used

Digitized by Google

this method of locking many times in places hard to get at and hard to keep from working loose and have found it to be very satisfactory. In case, after many operations, the nut cracks at the opening and closing it is but necessary to saw a slot in a new nut with the hack saw and place it as already described. This method comes quite handy about threshing machines, harvesters, and the like.

Still another simple and handy device for the

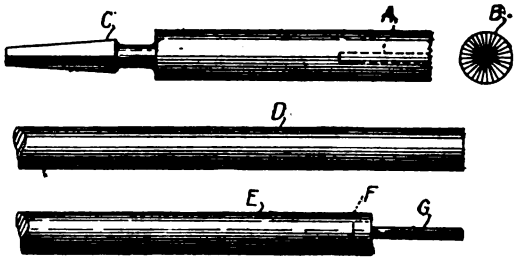

Fig. 3.

manufacture of small screws in an emergency is shown in Fig. 3. This consists of a steel rod with one end fitted for a brace, as shown at C, and the other end with a hole drilled into it as shown at A. The end of the tool has teeth arranged in such a manner that when the tool is turned to the right the metal from the rod will be cut away and the part not cut will run into the hole, A. The cutting edges, B, should be hardened and tempered in the usual manner. At D we have the rod of which we intend making the screw rolled at the end to allow of the tool being started more easily. At E we have the same rod with the exception that the tool has been worked on, forming the screw ready to thread. After threading, G, with the thread desired the

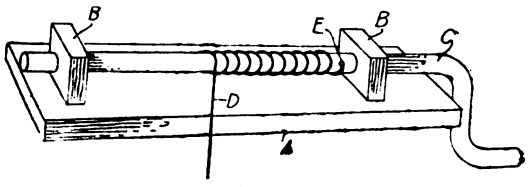

Fig. 4.

screw is sawed off at F and a slot sawed to permit of the screwdriver being admitted.

A number of tools of this kind can be made and placed in the tool box and will be found very handy, especially if no lathe is at hand. Of course it does not come up to the modern screw machines but will answer the purpose in a case of emergency, and we have many such cases from time to time.

Another small tool that any one can make is shown in Fig. 4. This is a small hand spring winder which can be made by any one in a few minutes. Very often a small spring is wanted for some particular purpose and if one were to carry an assortment of springs to meet the needs of all repair jobs it would take a truck to haul them. With a small spring winder and a few sizes of music wire it is possible to make many sizes and kinds of springs to meet the demands. We have at A a small piece of wood to which is fastened to it blocks, B, with holes in them to admit of the crank-shaped rod to be passed through them. The crank rod, C, can be made from different size rods, depending on the size of the spring wanted. Each rod should have a hole as shown at E to permit of the wire being held at one end while winding the spring. Now by revolving the crank rod, C, in the direction wanted and holding the coil of wire, D, tight, the spring will be formed as the crank, C, is rotated. As soon as the spring is wound the length wanted a file can be used to file the spring at hole, E, and rod drawn out leaving the spring ready to be formed for the job to which it is to be applied. This comes very handy in repairing smaller machines such as typewriters, guns, sewing machines, etc. The music wire can be purchased in rolls ranging from ¼ to 1 pound, and is not expensive. It needs no tempering after winding as it is given the necessary temper before being rolled and placed on the market. In case this wire is to be subjected to the weather it should be well oiled as it will rust quite easily.

In Fig. 5 we have a simple tool, yet quite useful and easily made from wire. Of course these tools can be purchased very reasonably, but many times it is not the price that hinders but the having them when wanted. The tool is a caliper made from about No. 9 wire. The ends from F to the ends are flattened and shaped up smooth, while the remaining

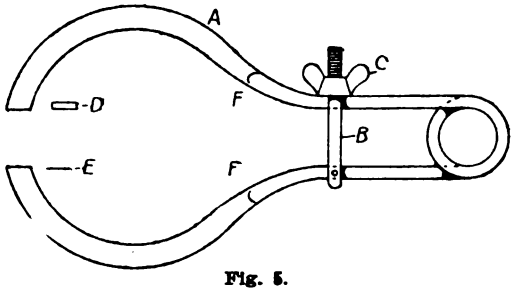

Fig. 5.

part of it is round. After forming it as shown the adjusting device is made of wire. It consists of a wire with one-half of the round filed away and the two sides placed together and threaded to take a wing nut, C. The bottom of the part, B, should be drilled for a small pin. By adjusting the nut, C, the jaws are opened and close as little or much as the user desires. The jaws, A, can be shaped at the ends to meet requirements as at D or E. D is the ordinary jaw for common work, and by making them both sharp-edged like a knife we can use them for a thread gauge, getting the bottom diameter of the threaded bolt. In case the caliper is wanted for some particular shape for a special job one will have to shape the jaws to have the tool to meet requirements. In case the work to be done is to be un-

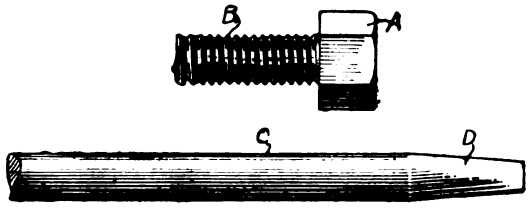

Fig. 6.

usually accurate the tool would probably spring until accurate measurements could not be taken unless it was made of heavy material.

One of the most annoying things that a repairman can be called to look after is a stuffing nut that some one has screwed down so hard that the threads are injured and it cannot be made to hold. I have found so many of them that I have devised a way to take care of them until a new one could be ordered, and many times these nuts will last for a long time. We have at A, in Fig. 6, a nut with threads B, worn or rolled down until when screw-

Digitized by Google

ing onto the packing it will jump back and refuse to tighten. To overcome this I made a small mandrel C, with the end D, slightly tapering. Now I placed the nut on the anvil with the end A downward, and placed the mandrel C, taper end into the nut and forced it into the nut with a hammer. This expanded the lower or threaded end of the nut sufficiently to make it hold its thread from the very start and the packing could be held just as firm as with the new nut. I have made repairs of this kind when machinery was shut down and the owner was lamenting over the fact that he would have to shut down until a new one could be ordered.

A simple device for lining down the center of a shaft or pipe is shown at D, in Fig. 7. The bar B, has a slot cut into it to slide through the locking nut C, which allows for the adjustment to fit the different sized rods or pipes. Now by placing the

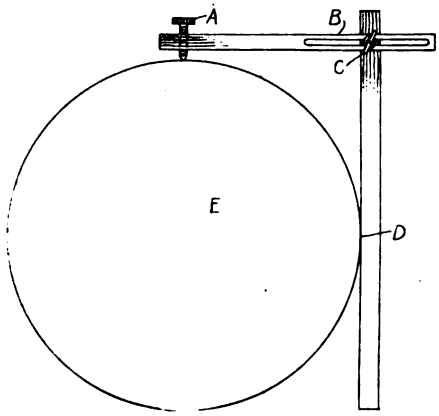

Fig. 7.

device over the shaft in such a manner that the scribe A, will be at center, and slide the instrument down the entire length of the shaft E, the center will be marked for drill holes or cutting a series of key seats, etc. In case the key seat is to be laid out with the width, it will be necessary to set the instrument and make two runs with it, leaving the space as desired for the width of the seat.

THE AUTOMOBILE ROUND TABLE.

Lubrication, Second-Hand Cars, Tires and Selling By Mail.

From G. D. Crain, Jr., Kentucky.—Most automobiles are so economical in the consumption of oil that it will pay the motorist to be a little extravagant along that line, in connection with frequent changes and replenishment.

Many an owner keeps filling up his crank-case with fresh oil, never stopping to think that the dirt and the residue from all that has been used before have not been eliminated, and that his oiling system is not going to give satisfaction in that condition.

Not long ago an automobile was brought into a garage because of engine trouble. The cause was located in a clogged oil strainer, dirt and other foreign matter having accumulated to such an extent as to make the circulation of oil very inadequate. It was a wonder that the car was running at all, and as it was the owner was lucky not to have injured his engine.

After the oil was drained out and the case cleaned, and fresh, clean oil substituted, the engine ran splendidly. All that had been needed was a fair chance to work properly, and this the automobile had not received.

Don't be so chary of wasting oil by draining it out of the case that you will interfere with the efficiency of your car by not having the oiling system working properly.

Selling Second-Hand Cars.

One of the best ways to sell used cars, in the event that the automobile concern is big enough to justify this plan, is to have one man completely in charge of this department. The idea is that his work is to be concentrated on second-hand machines, and therefore he is not expected to attempt to sell new cars; on the other hand, he is even to compete for sales with them, and to get business for second-hand automobiles instead of new ones, if he can convince the customer that it is to his interest to buy the used car. This creates a strictly competitive condition between the salesmen who are handling new cars and the man who is exclusively employed to sell old ones, and makes for better work all around.

Another phase of the question is that the salesman who doesn't have to blow hot and cold, and argue first in favor of one car and then for another, is able to do his work better. The man who is selling new cars—on which the main effort of the automobile company is obviously being expended—cannot usually work up much enthusiasm over an old machine of another make. He will be a "bear" as far as it is concerned, and will be inclined to regard it as a rather undesirable proposition. Prospects for the sale of such cars will not impress him nearly so favorably as if they were in the market for new cars.

On the other hand, the salesman whose sole job is to convert old machines into cash isn't worrying about whether the company sells a single new car or not. He is not interested in them, at all. He studies his stock, puts it into the best possible condition, and by working with the cars and driving them he becomes just as enthusiastic as though he were selling machines fresh from the factory. He can talk more convincingly than the other type of salesman, because he is sincere in what he says about the merits of what he is offering.

This plan of dividing the work along this line has been used by a number of successful automobile concerns, and because it is based on common sense it is bringing unusually good results.

Tire Service Stunts.

It is wonderful how far competition will drive members of any trade, in creating service which they are willing to offer their customers.

Tires have been the subject of more competition in connection with automobile supplies than any other item, and consequently tire dealers will go further to give service than business men in any other line that can be named. Here is the development of the service situation in one typical city:

First, the dealers offered to send out a man to change tires for the customer, at a charge of 60 cents an hour, this including the time consumed on the road. Second, this plan was extended so as to give free service to customers who were using the tires principally dealt in by the concern furnishing the service. The old charge was continued for tires of other makes. Third, the free service feature was extended to cover every kind and variety of tires. You can now get tire changes in that city from any

Digitized by Google

one of several dealers without any expense, no matter what tires you have on your car.

The service has also been extended as to the territorial limits. At first the dealers agreed to send their machines as far as 10 miles from their stores, which meant about five miles into the country. Now they will give service anywhere within a radius of twenty-five miles, and one dealer, particularly anxious for business, has agreed to send anywhere the customer wants him to come, no matter how far, and no matter how little business there is in it for him!

One of the dealers in the city referred to has figured the cost of handling this business, and finds that it costs him 13 cents to make a run. If he gets only a tube repair, the profit on this operation will just about enable him to break even on the service. If a tube is purchased, or a case required, or a blowout requires a vulcanizing operation, then there will be a little money in it. But it is easy to see that competition along service lines is making the margin of profit rather slim for the members of the tire trade.

Can Business Be Forced?

The extreme efforts of tire dealers to hold business by giving unusual service were referred to above. Now and then, however, one finds an automobile concern going to the other extreme and trying to force people to patronize it, by withholding service.

For example, a certain automobile dealer, who has the agency for an unusually popular car, lost his grip on his trade by failing to run his garage in a business-like way. Customers could not get attention, repairs were not promptly made, and the dealer ultimately found that his whole business had been undermined. He could not get the repair business on the cars he had already sold, and was thus deprived of the revenue involved in this way. With sales of new cars falling off, he needed the other business badly.

He wrote letters to old customers, asking them to come back, and promising better service, and when they did not return in number, he adopted the plan of refusing to furnish parts to other repairmen who had work to do on cars which he had sold. Thus far this plan has not worked any better than the other, and about the only result which one can be sure of is that people are not going to buy any more cars of the first dealer, if they know his attitude on the subject of supplying parts.

Novelty Advertising.

Dealers in automobile supplies, especially if they are just starting in the business or have changed their locations, often need to attract the attention of the motorists of their community, and to get them to the store. Once an owner has formed the habit of coming in, and has familiarized himself with the location of the place, his business is almost assured, assuming that the store is not inconveniently located.

Hence offering a novelty of some kind to get the autoists to come in is often good business. A concern recently sent out a circular letter to a large list of owners, describing its stock and service, and offering to supply each of those receiving the letter with a tube bag, free, if the card which was enclosed was presented during the current month. The returns from this stunt were good, and inasmuch as a great many new customers were brought in through this medium, the dealer felt that the expenditure for the bags was well worth while.

Another good way to get customers started to buying is by offering special values on certain items from time to time. Cutting prices is not a good policy, as a permanent proposition, but it undoubtedly attracts attention. One big supply store constantly has goods which are in regular demand shown in its windows at reduced prices, and these attractive items have the effect of getting a great many motorists to come in and see other goods which may be sold at the normal margin of profit.

Selling by Mail.

So many automobiles are owned in the country that there is a good opportunity for the dealer to do business with their owners through the medium of the parcel post. A number of automobile supply dealers have built up a productive mailing-list of owners in the country within a reasonable radius of their stores, and by advertising in local newspapers, sending out circular letters, etc., they are able to get constant returns in the way of orders for specific items of goods. It is a big convenience to the country owner to get supplies that he needs in this way, especially from a nearby dealer; and the concern which covers its own local territory for mail-order business will capture a great deal of it that otherwise would go to the big houses hundreds of miles away.

A FEW REPAIR KINKS.

To Drill Special Holes, Holding the Drill and Pulverizing Glass.

From N. G. Near, New York.—Most automobile owners who do their own repairing own a breast drill and a few of the standard sizes of drills, which suffices for most work. But, when they want to drill a special size hole they are "up against it."

There are two ways to drill a hole of odd size,

Fig. 1.

either with a standard drill or by means of a home-made drill forged from drill rod. With a standard drill, simply grind the point over a little (off center) as indicated in the drawing, Fig. 1. The size of hole will then be approximately like A-A. Of course, a standard drill cannot be made to drill a hole smaller than itself without grinding down the

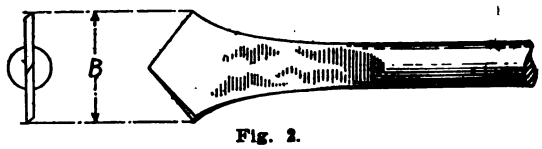

Fig. 2.

drill, which would be a foolish and expensive process.

The other way is to forge drill rod to the shape indicated in Fig. 2, with distance B, equal to the diameter of the hole to be drilled. Grind accurately so that the point of the drill will come exactly in the middle, and as for cutting angles, the best way to get them right is to follow the cutting edges on the standard drills. Make the angles just the same. Heat to a cherry red and harden. Draw the temper to a straw color, or slightly softer, and the drill is

Digitized by Google

complete. Judgment, of course, must be added in both cases.

Sometimes it is desirable to enlarge the bottom of a hole for purposes of anchoring solidly. Fig. 3 shows how this can be done very easily with the

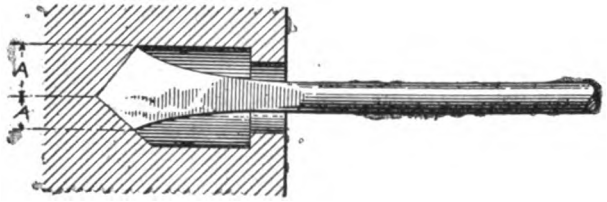

Fig. 3.

same drill that was used to start the hole. Simply grind the forged drill "off center," as at A-A, just as the standard drill, Fig. 1, was ground. The diameter of the enlarged part will then be as shown. The finished diameter can be computed to a nicety

Fig. 4.

beforehand, before the drill is even started, as is obvious from observance of the sketch.

How to Hold a Small Drill.

I show herewith my scheme for holding a small drill in a common brace-and-bit chuck. Saw two slits, C and D, at right angles in a 3/16 inch rod E, of

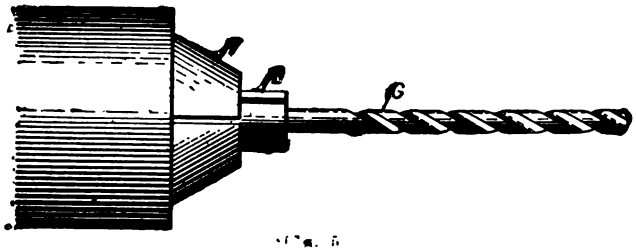

Fig. 5.

suitable length which has first been turned down in "steps" as shown in Fig. 4. Then insert the split piece E, in the chuck F, at the suitable holding point, insert the drill G, and clamp, Fig. 5. Care must be

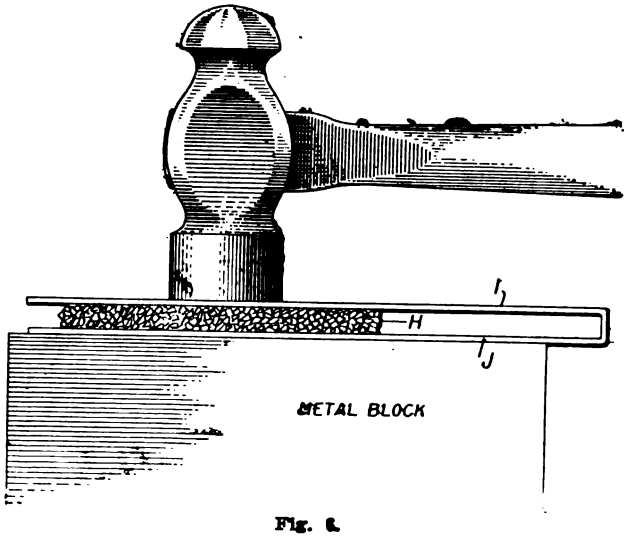

Fig. 6.

exercised in sawing to center the drill as closely as possible.

Pulverized Glass for Valve Grinding.

It may not be very well known among automobile men that pulverized glass is an excellent material for valve grinding. The trick is, how to pulverize the glass in safety. The best scheme I know for pulverizing in safety is shown in Fig. 6. Place the glass H, between two pieces of sheet tin, I and J, or other light sheet metal, and hammer on top as shown. There will be no danger of getting glass particles in the eyes or face.

REPAIR HINTS.

Something About Worn Engine and Other Automobile Bearings.

A car that has been two years or more in use often requires some repairs. The engine being the most important part of the car, it is advisable to give it attention first. The eliminating of any slackness in the bearings is not at all a difficult job, but at the same time it needs to be done carefully.

Only one special tool is needed for the job, that being a scraper for the bearings. It is usually made out of an old half-round file, forged in the form shown in Fig. 1. Grind the face, A, flat, or better still, grind it hollow to within 1/8 inch of the edges, BB, after the style of a hollow-ground razor. The end with the cutting edges is hardened, and is then finished off on an oilstone. These scrapers can be purchased at any shop stocking engineers' tools. If it is only intended to take up slackness in the big-end bearings it will not be found necessary to remove the engine from the chassis, assuming there is an inspection pit in the garage, or that there is no objection to lying under the car.

Dismantling.

First remove the radiator, and all connections to the cylinders. Lift the cylinders off and remove the crankcase bottom, taking care to drain the oil from the latter before taking it down. If the main bearings are to be taken up also it will be necessary to remove the remaining part of the engine from the chassis and to take off the flywheel. Before completely dismantling see that all the timing wheels are marked, and such other parts you may not be sure about when it comes to reassembling. If it has not already been done, mark the connecting rods so that each may be fitted to its original journal, and in the same position. Also mark the bearing brasses in the connecting rod ends, the gudgeon pins and the pistons.

The Journals.

Examine the crankshaft journals. Sometimes they will have worn a little rough and require polishing. If not in a bad condition obtain a long piece of smooth emery cloth about an inch wide. Give it one complete turn round the journal, and impart a steady movement backwards and forwards, applying a little oil. This will soon remove any slight uneven wear on the surface. Sometimes the journals will have worn oval a little. The best treatment is grinding. In case this cannot be done, remove the worst of the oval formation with a dead smooth file, testing it frequently with calipers. Then finish off with emery cloth.

The Bearings.

Begin on the main bearings. The greater part of the wear will obviously be on the lower half. It will therefore be necessary to raise this to bring the crankshaft to its original position. Remove both brasses and file the flat faces until they fit the journal a little tight when clamped around it. It is im-

Digitized by Google

portant that this should be done properly and evenly. Be very careful not to remove too much metal.

If the brasses are now replaced in their original position they will be slack as regards the outside diameter. To compensate for this condition the bottom brass must be packed at the back with brass foil. The latter can be obtained in various thicknesses. For our requirements 4-1000ths of an inch is most useful; cut a piece the full length of the brass between the flanges, but only wide enough to cover about three parts of the circumferential surface. This can be laid at the back of the brass, but it is best soldered, at least along one edge to prevent it moving.

Replace the brasses, and screw down the cap without the crankshaft being in position. Try to move

Fig. 1.

or turn them. If they are still loose, more packing must be added, but at the back of the other half. Before screwing down the cap tightly measure the inside diameter with calipers. Now screw down firmly, and see if there is any perceptible decrease in the diameter. If there is, the packing is too thick, and should be reduced with a file or replaced by something thinner. It may be possible to take a little more off the flat faces, providing it does not require too much scraping out to fit the journal. Take the case of a connecting-rod bearing, Fig. 2. When the bolts are drawn up tight the faces of the brasses, C, and those of the connecting rod and caps, D, should be close together, so that nothing could be passed between them. At the same time the brasses must not be pinched at EF.

Bedding In.

Now proceed to bed the crankshaft into its bearings. Probably there are three, and it is of the utmost importance that they should be on the same level. The brass should be forced down until its back is well in place. This can be tested by smearing the casing with marking composition. The latter is made of either red lead, or lamp black and oil, mixed to the consistency of a thick paste. It should only be applied very slightly. When the brass is forced down it is marked where it touches. The high places are removed until it is marked evenly all over.

Smear the crankshaft lightly with the marking, place it in its bearings and revolve it several times. On being removed again the bearings will be marked in several places where the journals have touched. Remove a little of the metal with the scraper where it is most heavily marked. Use the scraper with a light circular motion in the direction of the curve of the surface, as indicated by arrows in Fig. 3. Continue the process until an even bearing surface has been obtained on each brass. The journal must touch every part of the bearing evenly, not merely at the bottom. This operation will probably take some hours, or even a day to complete, so do not get impatient if it is found tedious. The better the surface the longer the subsequent life of the bearing.

Having completed the work so far, now proceed with the other half of the bearing. It will be obvious that the crankshaft is first fitted into the top half of its bearings. The top half of the crankcase is inverted for fitting main bearings. Take one bearing at a time. Bolt the other half of the bearing down until it is just possible to turn the crankshaft. Revolve the latter several times, having first smeared it with marking. Remove the half-bearing and scrape the high places, i. e., those most heavily marked. Continue the process until the crankshaft can be turned freely—at the same time marking the bearing evenly all over—when the bolts are pulled up as tightly as possible. There must not be the least slackness, and a very good bearing surface must be obtained. This half has the greatest amount of wear when the engine is running. Scrape all the bearings, clean them thoroughly, and smear with clean engine oil before bolting them up finally. The crankshaft should have just an inclination to "stick" if the work has been properly carried out.

Big-End Bearings.

To fit the connecting rod big-ends, proceed precisely as with the main bearings. File the faces of the brasses and pack the backs. If very little packing is necessary only use it at the back of the brass in the connecting rod, and none in the cap. Referring to Fig. 2, it is exceedingly bad practice to file the machined faces, B, of the rod itself.

Bolt the rod and its brasses together before trying it on the crankshaft, to see there is no slackness or that the bearing is not deformed when the faces,

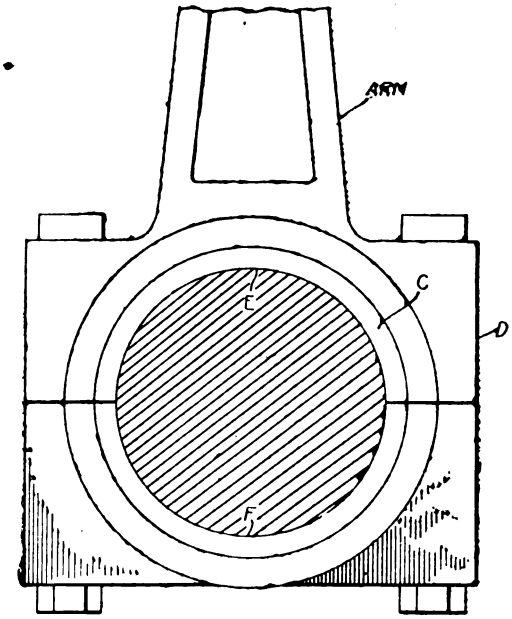

Fig. 2.

D, are drawn close together. Being satisfied on this point, now try the connecting rod on the crankshaft, having first smeared the journal with marking. Tighten the bolts up until it is just possible to turn the rod on its journal. Scrape the high places as before and continue the process until a good bearing surface is obtained. When finished, it should be possible to draw the bolts up quite tight without any tendency to grip the crankshaft. As a final test, clean the bearing and journal and assemble it, having lubricated it with engine oil. Place the connecting rod on its top dead center. With perfect fitting it should just fall over by its own weight.

Before assembling the engine examine the small-

Digitized by Google

end bushes and gudgeon pins. If the latter are at all slack they will cause a knock when the engine is running. It is possible to obtain from the makers of most cars gudgeon pins which are over standard size. If new ones are obtained and found a little too large the bush will need scraping out until the new pin fits properly.

The Valves.

As a rule with second-hand cars the valves are found much worn and grooved. No trouble is taken to turn the faces down true before grinding in. If the grooves are removed with a very smooth file while the valve is revolved in a lathe, a very satisfactory surface can be obtained. With a little care

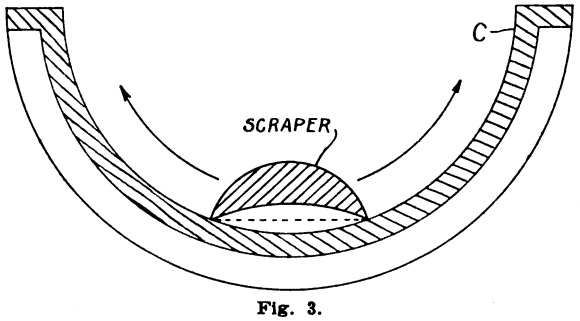

Fig. 3.

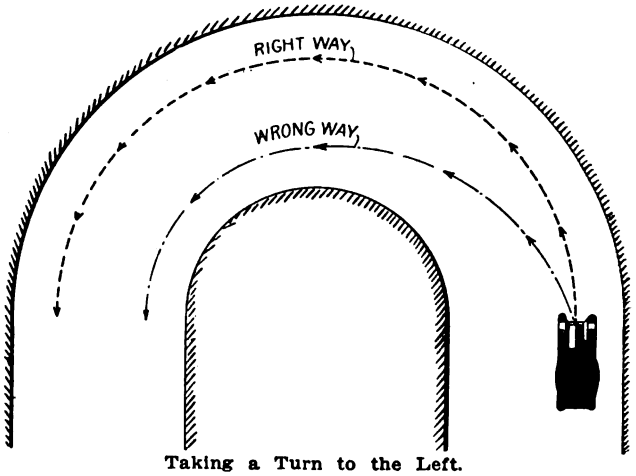
a valve can be filed up fairly true in the vise. It is very seldom indeed that the valve seats in the cylinders need trimming. Many repairers are very fond of cutting the seating, much to the detriment of them.

When grinding in valves remember that the smallest leak quickly increases and lessens the compression in the cylinder. Use very fine emery powder, with a good supply of oil for grinding. Get an even surface all round the valve and the full width of the seating, not merely on the top or bottom edge. Finish off with scarcely any emery powder in the oil. Some of the grinding compositions sold are very satisfactory, but should be used sparingly and with plenty of oil. Before finally replacing the valves thoroughly clean off all traces of emery and oil with a paraffin rag. Especially give attention to the valve guides, or excessive wear will take place.

Assembling.

When assembling the engine be very careful that all parts are clean and free from grit and dirty oil. The piston rings must have their split ends spaced equally apart to prevent leakage and loss of compression. It is advisable to remove the rings and clean off the carbon in the grooves. This will ensure the rings being in contact with the cylinder walls all round. Examine all the inlet, exhaust and water joints, and renew where necessary. Special care should be taken with regard to the induction pipe joints. Any leakage past these will make it difficult to start up the engine. Examine all bolts and nuts to see if the threads are in good condition. When replacing these pull them up tightly, and put in split pins where needed.

Carburetor and Magneto.



Take the carburetor apart and clean it out thoroughly. Grit will invariably be found in the float chamber. Examine the float for leaks. By shaking it one can hear if any gasoline is inside. To find the leaking place, hold the float under boiling water and air bubbles will rise. The faulty place must be carefully and very lightly soldered.

The magneto is generally considered a sort of delicate mystery, but it is quite simple for an amateur to take it apart. All parts should be cleaned and the contacts also. It will make a difference to the running of the engine. The contacts should be adjusted to the gauge attached to the spanner supplied by the makers. If too wide apart, the engine will be difficult to start. See that the magneto is replaced to its original marking to get the setting correct. It is quite likely the engine will be difficult to start for the first time. A very little gasoline injected in the cylinders before replacing the plug will assist. If the instructions given are carefully followed the owner will be greatly pleased with the improvement in the running of the engine.

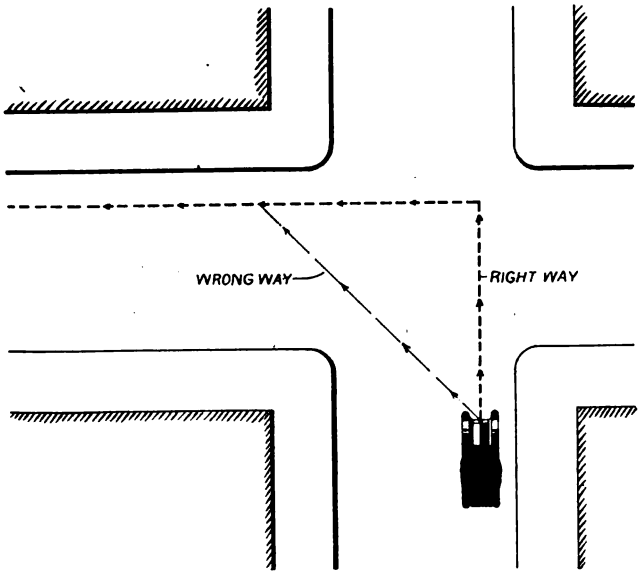
ROAD RULES.

More Accidents Due to Wilful Neglect than from Ignorance.

The roads of New Hampshire are as crooked as the proverbial "ram's horn." They must necessarily be so to avoid as much as possible the hills and valleys that give the "Granite State" its just claim for rare scenic beauty. But in a recent somewhat extended automobile tour there the writer could not fail to note the utter lack of compliance with the ordinary and rational rule of sounding the signal when approaching a sharp turn in the road. Again and again approaching automobiles appeared around sharp turns in narrow roadways without having given the slightest warning of such approach, and frequently the passing was made only by the quickest possible action upon the steering wheel. Unfortunately, the heedless if not criminal driver who ignores the rule of the road is less

Taking a Turn to the Left.

liable to suffer than the one who acts upon it. Hearing the signal, he can keep to his own side of the road, but the one who gives it may not have any such impulse.



Road driving rules are not complicated or difficult, and more trouble is made in a day from wilfully violating them than in a month from ignorance of them.

Those who are familiar with city traffic regulations and apply them as well on country roads, will not be likely to encounter difficulties. The burning of at least three lamps, including two head or side and one tail lamp, is enforced from sun-down to sun-up in practically every state. In many cities the headlights are not allowed to glare and most cars are now fitted with a dimmer.

The driver of a car should be careful to observe

Digitized by Google

the rules of the road, for in case of accident, damages cannot be collected if he can prove that he followed these rules. Throughout the United States, the invariable rule is to keep to the right; in England it is the opposite. In passing a slower moving vehicle going in the same direction, swing out to the left. It is a courtesy, and in some localities even a law, that one traveler shall not hold the road to the same exclusion of other travelers, but shall turn whenever possible, to permit the vehicle following him to pass. Many accidents are caused by vehicles crossing in front of others. The rule is that one who attempts to pass another on the highway going in the same direction has the right to do so in such manner as may be most convenient under the circumstances, and where damage results to the person passed, the former must answer for it, unless the latter, by his own carelessness, brought the disaster on himself. The same rule is applicable in

The Wrong Way is the Usual Way.

passing a standing vehicle approached from the rear.

In many of the larger cities, as in New York and Chicago, all north and southbound traffic is given the right-of-way over traffic moving east and west. The rule does not exist in smaller communities nor outside of city limits.

A little diplomacy and good nature are invariably advisable, and if every motorist would show the drivers of horse vehicles a little more courtesy, it would bear fruit and horse drivers would be more willing to give a fair share of the road.

Go slow at turns in the road and thus avoid a collision with the vehicle that may be coming toward you. Go slow at cross roads also, for another car may be coming across at the same instant. Take bridges, embankments and narrow roads at a slow pace, keeping the car under instant control. Bridges in the country are apt to be shaky, and it is dangerous to cross them at speed, besides being against the law.

Slow down when a horse ahead shows signs of fright, and if necessary stop the motor. There are laws in some states compelling an automobile to come to a stop as soon as the driver of a horse-drawn vehicle holds up his hand, and there is no reason for the motorist not to obey it.

Raise the right hand when about to make a stop or turn, as a warning of your intention, to vehicles in the rear. Always regard this signal when it is made by the man in front. Another signal that is coming into use is the raising of the left hand with two fingers extended, as a warning to cars coming that they will find a police trap.

Do not follow a car too closely, for it may stop without warning. When a car comes up from behind, and shows signs of desiring to pass, give it fully half the road by swinging to the right.

Drive slowly through the towns and villages, and when passing schools, churches, bicyclists or pedestrians. Stop when there is an accident, whether it is your fault or not. Render all the assistance possible, and as a safeguard get the names and addresses of the witnesses.

Excessive sounding of the signal is evidence that the motorist is a novice. Sometimes, as in the presence of a frightened horse, it may be better not to use the signal at all. No accepted rules exist in regard to the meaning of horn blasts, but it is reasonable to assume that prolonged signals indicate that the car behind is going to pass and desires a clear road. Bear in mind that a nervous driver may pull the wrong rein, that a pedestrian cannot make up his mind in a hurry when he wants to cross the road, that it is your business to avoid danger, not the other man's, that the road is free for all, and that it pays to be courteous. Do not use the electric headlights turned to the "bright" position when approaching or passing a car or other vehicle on a narrow road, unless you are traveling in the same direction. The light confuses and may result in a serious accident.

The two accompanying illustrations show frequent and dangerous practices. A driver should be arrested for violating the sensible rule of not keeping well to the right side of the road or street when making a turn to the left. As a matter of fact, he never or seldom is taken to account for these offences, although accidents have occurred again and again when they have been overlooked.

SELF STARTERS.

More About Some of the Popular Devices and How They Work.

BY C. P. SHATTUCK, M. E.

No. 3.

The control of the current flowing from the storage battery to the electric motor of the starting system is by a form of switch and these vary considerably. The location of the control member also varies, some being mounted on the instrument board, others in the heel board, while some manufacturers of motor vehicles place the control on the steering column under the wheel. When the last named installation is utilized the control is incorporated with the ignition and other control units. The control or switch of the motor starter is not always separate from the motor but is mounted on the housing of the unit with the contact making part attached to or incorporated with the shifting rod of the pinion. Starting switches may have one or more contacts. The first contact permits of but a small amount of current to flow to the motor, causing the pinion to rotate slowly. This reduction in the strength of the current is generally accomplished by inserting a resistance in the circuit, assisting the pinion to mesh with the flywheel gear. A further movement of the lever or pedal makes a full connection through an-

Digitized by Google

other contact, allowing the necessary amount of electricity to pass to the motor.

A simple form of control is shown at Fig. 24 which illustrates the Bijur system. In includes a series wound motor, a pedal switch and a storage battery. As may be noted the application of the motor's energy is through suitable reduction gears to the pinion which is meshed with a toothed flywheel. The switch is actuated by a pedal which when depressed by the driver, closes a contact and also shifts the motor gears into mesh with the teeth on the flywheel. The construction of the switch provides two arms, 1 and 2 (Fig. 25), which are connected to-

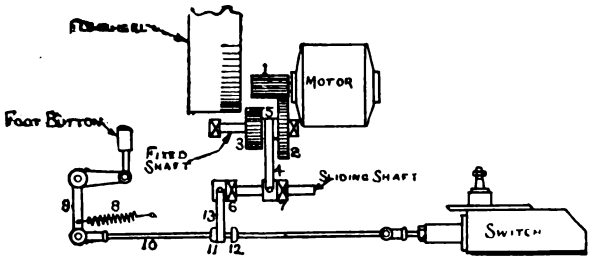


Fig. 24—Control of Bijur Starting Motor by Foot Button.

gether through a resistance, 3, but which are otherwise electrically insulated from each other.

Operation of Bijur Switch.

When the pedal is depressed, the switch rod is moved outward, and the first action is to bring the contact arm 1 and 2 into contact with the advance fingers 4 and 5. When in this position a circuit has been established from the storage battery through the switch and the motor. The path of the current may be easily traced. Beginning at the storage battery the current traverses the wire, 6, through the main contact, 7, of the switch, then through the advance finger, 5, to the arm, 1, thence through the resistance, 3, to the arm, 2, through the advance finger, 4, the main contact, 8, thence through the wire, 9, to the motor. The current then passes through the motor armature and field coils and then

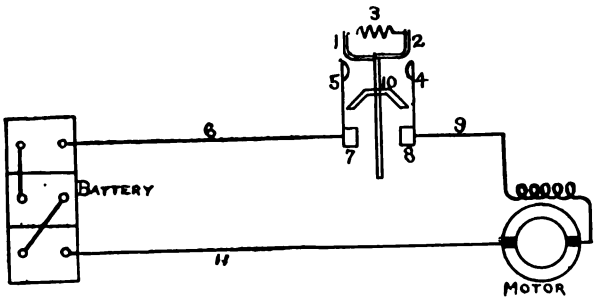

Fig. 25—Diagram Showing Connections made by Switch of Bijur Starter.

back to the battery through the wire, 11. The circuit being complete, the electricity passes through the motor.

The value of the current through the motor is limited by reason of the resistance which has been placed in the circuit, the resistance being sufficient to cause the armature to rotate at a very low rate of speed, resulting in rotating the pinion into mesh with the flywheel.

When the pedal attains its final or maximum position, the main switch brush, 10, is across the contacts, 7 and 8, and the current from the battery is shunted around the resistance. The circuit from the storage battery is as previously described, except at the switch, in that the current entering the switch through the main contact, 7, passes across the switch brush, 10, to the main contact, 8, thence through the motor to the storage battery. With the switch in this position the resistance, 3, has been eliminated from the circuit and the motor is directly connected to the battery. The resistance is not cut out until the gears are fully meshed. After the engine starts to operate under its own power, and upon releasing the starting pedal, a contracting spring moves the gears and switch to their normal or non-operating position.

Fig. 24 shows the arrangement of the components. The pinion, 1, of the motor is constantly in mesh with the gear, 2. This gear has an over-running clutch, the inner member of which is rigidly connected to a pinion, 3, which is designed to mesh with the flywheel. The gear and pinion are mounted on a stationary shaft and move horizontally along it. A movable member, 4, engages the trunnion, 5, on the sliding gears and is loosely connected to the rod which is actuated by the pedal, and which in turn operates the sliding gears and the starting switch. The movable member, 4, is attached to a horizontally moving shaft. As illustrated, a spring, 8, retains the gears and the switch in their normal off position when the pedal is not touched or depressed. Depressing the pedal causes it to move downwardly

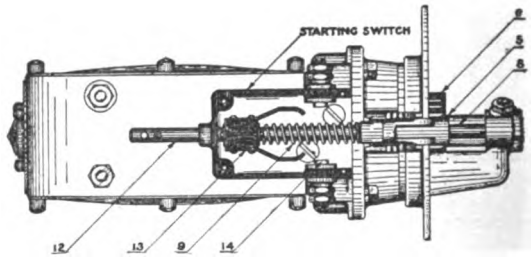

Fig. 26—Contacts of switch utilized in Gray & Davis System.

against the tension of the retracting spring, and this vertical motion is transmitted through the bell crank, 9, moving the rod, 10. Mounted on the rod, 10, are two collars, 11 and 12, which engage the member operating it with the trunnion on the sliding gears. As the rod, 10, moves forward, the switch rod moves before the collar, 12, picks up the member, 13. This arrangement allows the motor to start rotating slowly before the gears move into engagement. After the rod has moved sufficiently to permit of the initial switch contact being made, the collar, 12, picks up the member, 13, and the gears are then moved forward until the pinion is fully meshed with the flywheel at which time the resistance is cut out.

Bosch Switch.

The motor starter manufactured by Bosch Magneto Company employs a switch that is operated by means of a pedal which is moved downward to make the electrical contacts. The wiring plan of the starter and switch is shown at Fig. 29, and the insulating plate which forms one side of the starting switch carries the three terminals for the battery and motor cables. The two heavier cables are for the main circuit, and the single small cable for the shunt circuit. When the switch plunger is operated, the current from the battery first flows through the field windings of the motor, after which it is diverted through the shunting cable and armature of the motor. The operation of the system was fully explained in the previous installment.

The motor starter manufactured by Gray & Davis,

Digitized by Google

Inc., is an example of the switch being incorporated with the motor but operated by a pedal. The switch is illustrated at Fig. 26. The pinion meshing with the flywheel is operated mechanically; that is, the pinion is slidingly engaged. The mechanical and electrical connections are practically made at the one and same time. Attached to the switch rod is a shifter fork which moves on an intermediate shaft a sliding pinion. The intermediate shaft carries an intermediate gear with an over-running clutch. When the pedal is operated, the movement of which moves the sliding pinion into engagement with the flywheel gear, the movable switch member makes contact with the stationary switch contact and current flows from the battery to the motor. The shifter fork on the switch or shifter rod is provided with a spring which tends to keep the contacts out of engagement as when the starting pedal is released. This type of motor starter is of the enclosed design; that is, is known as the enclosed flywheel type.

Aplco Motor-Generator Switch.

Fig. 28 shows the wiring plan of the switch utilized with the Aplco motor-generator which operates

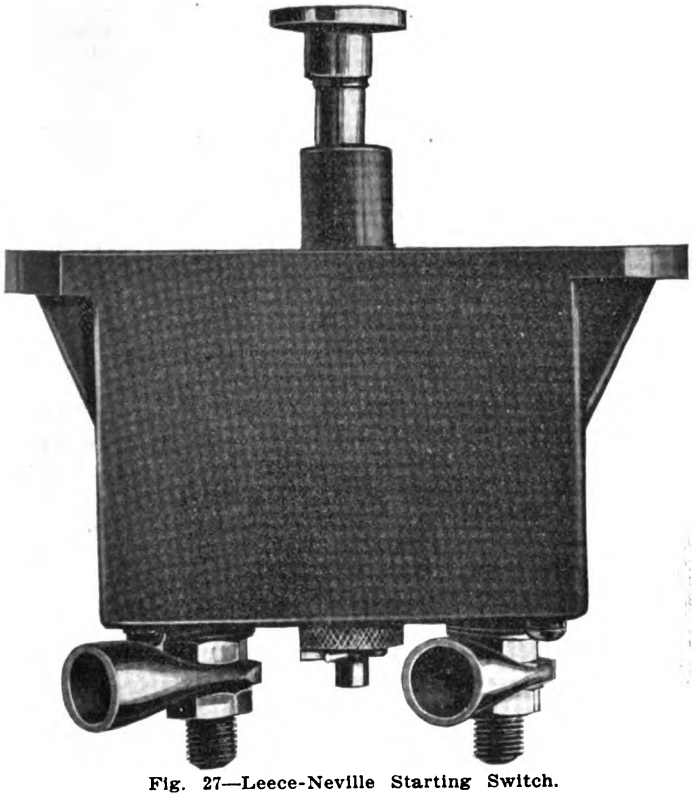

Fig. 27—Leece-Neville Starting Switch.

as a 12-volt unit as a starter and as a six-volt unit as a dynamo. The motor-generator is connected across the terminals of the battery through the starting switch when employed for starting. The 12-volt current is obtained by pressing the starting pedal down or starting position at which time the two six-volt cells are connected in series. Upon releasing the pedal to the running position the cells are connected in parallel and are charged by the dynamo as a six-volt unit.

With the mechanical pinion shift of the Westinghouse starter, one motion of the starting pedal starts the motor at low speed and cuts off the current supply until the gears have meshed, then the full voltage is thrown out of the motor and continued until the pedal is released. Releasing the pedal disengages the pinion and cuts out the current supply. With this system an over-running clutch is employed. The mechanical shift switch can be mounted separately, or on the gear case with the contact making part fitted in the pinion shift rod. The latter method is favored as it is stated to prevent all lost motion between the operation of the switch and

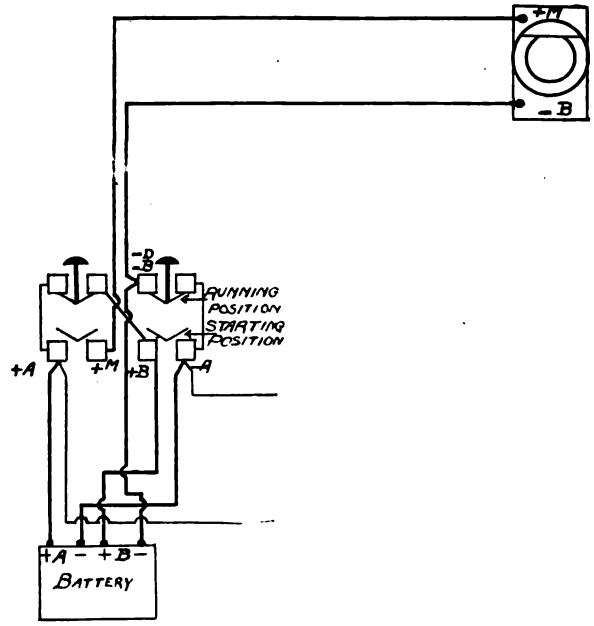

Fig. 28—Illustrating the Running and Starting Positions of the Aplco Switch.

that of the gears. The stationary part of the switch consists of a metal casting containing the contacts and a starting resistor in ribbon form inside the case. The moving contact, arranged for mounting on a shift rod, provides a rubbing, self-cleaning contact for the temporary connection and a butt contact for the full power connection.

Automatic Gearshift.

With the automatic gearshift, which was fully described in the previous installment, either a foot-

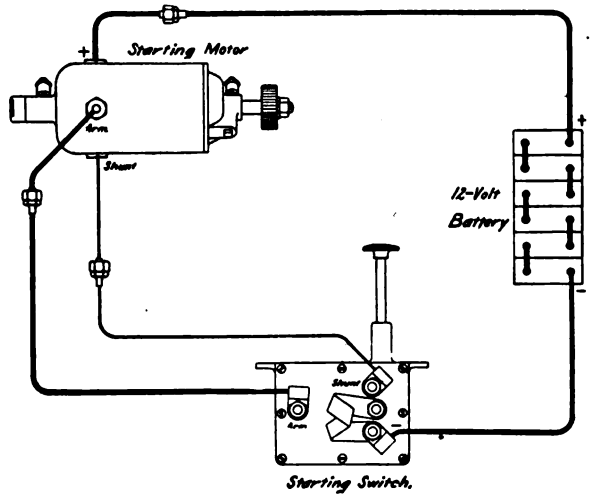

Fig. 29—Wiring plan of Bosch Motor Starter Switch.

operated switch or a push button controlling a solenoid switch can be used, the type depending on the service expected. The switch for ordinary service has a drawn metal case and a face plate for mounting either on the dash or the footboard. In either type a motion of ¼ inch closes the contact. The foot pin of the heavy service switch can be removed

Digitized by Google

by the driver when he leaves the car, making it impossible for anyone to operate the switch.

In the electro-magnetic pinion shifting system, either a push button is used to close the electrically operated switch, or a switch similar to that employed with the automatic pinion shift is used. Closing the main switch first starts the motor at low speed, then operates the electro-magnetic pinion shift. This in turn cuts off the power from the motor so that it rotates from its own momentum until the gears mesh, then throws the full voltage on the motor. Releasing the push button opens the electrically operated switch which cuts off the current from the motor and returns all components to their normal or non-operating positions. The electrical connections are so arranged that in case the operator fails to release the push button, the electrically operated switch will open.

Starting and Running Torque.

There is considerable difference between the power or torque required to start an engine and that needed to keep the crankshaft rotating once it is started in its movement. It is practically the same principle that requires four horses to start a heavily loaded vehicle that two can haul after the wagon is in motion. Fig. 31 is of interest as it shows a chart illustrating the torque required to turn a four-cylinder motor having a bore of 3¾ inches and a stroke of 5¼. The foot pounds required for a stiff motor are greatly in excess of an engine that has been limbered up with service.

The current consumption or momentary rush of

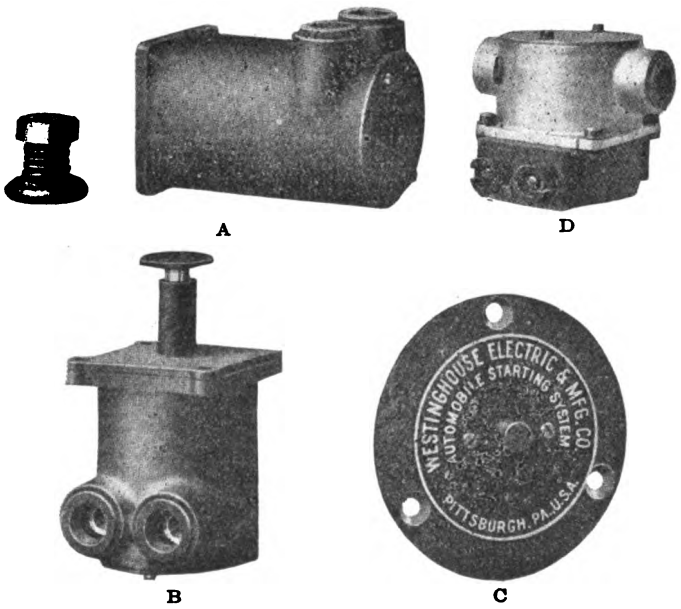

Fig. 30—Westinghouse Starting Switches: A, for mechanical pinion shift; B, automatic pinion shift; C, push button type; D, electrically operated.

electricity at starting is given out by the manufacturer of the starting systems, but one authority holds that exact information has not been forthcoming on this point. A well known electrical authority conducted a series of experiments with a starting system, using a four-cylinder engine having a 3¾-inch bore and 4-inch stroke, giving a cylinder displacement of 177 cubic inches. It was found that the first rush of current in starting was 236 amperes, that the peak of the curve was at the time the starter pulled the engine over the first compression. The time lapsing between the closing of the switch and the passing over the compression was .043 seconds, and the torque exerted by the motor with the current of 236 amperes was 28 foot-pounds or 84 pounds at the engine shaft. The tests developed the fact that the torque required to pull the engine over the first compression was 35 foot-pounds, and that the difference, 39 foot-pounds, was utilized in overcoming the inertia of the motor and engine. As

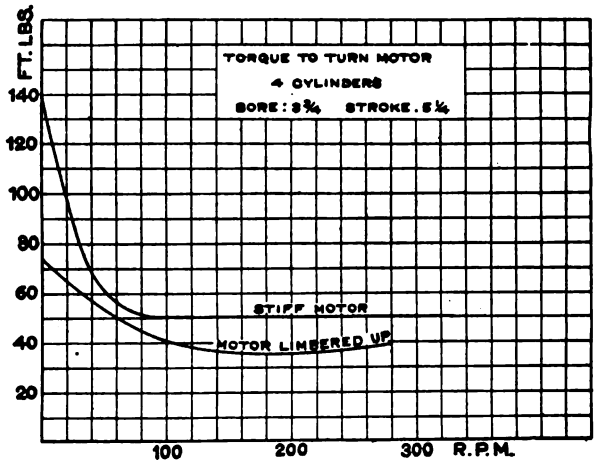

Fig. 31—Chart showing pull required to start and run a stiff motor after it has been limbered up.

soon as the crankshaft of the engine began to rotate the current consumption dropped to 63 amperes. It is estimated that a normal start requires about half a second.

(To be continued.)

AUTOMOBILE CLUTCHES.

Their Importance and a Comparison of the More Recent Designs.

W. F. Herst, M. S., before the New York Society of Automobile Engineers.—The development of the automobile clutch should receive far more attention than it is given by the average automobile engineer. Nothing is more objectionable to the occupants of a car or more destructive to the car itself than a clutch that cannot be smoothly engaged. A clutch that grabs not only operates to the detriment of the motor but will in time destroy the transmission and rear axle gears, as well as injure the axle housing, drive-shafts, springs, wheels and tires. A bad clutch, carelessly operated, will reduce the life of the rear tires at least 20 to 25 per cent., loosening the tread on the tires and permitting small cuts to form sand blisters, with the usual result.

Care should be exercised in designing the clutch to see that it is not of too great capacity. Experience has proved conclusively that the best operating clutch is one that will just hold the maximum power developed by the motor. It is also very important to have a clutch that releases freely and quickly. A clutch that does not release properly will often prohibit quick shifting into second gear on a hill, with the result that the car loses momentum, and it becomes necessary to shift into low gear to climb a hill that should ordinarily be taken on second. Such a defective clutch will also cause clashing of the gears in shifting, premature gear replacement becoming necessary and the quality of the transmission being unfairly criticized. No transmission will withstand such abuse long. In this connection it seems advisable to provide always

Digitized by Google

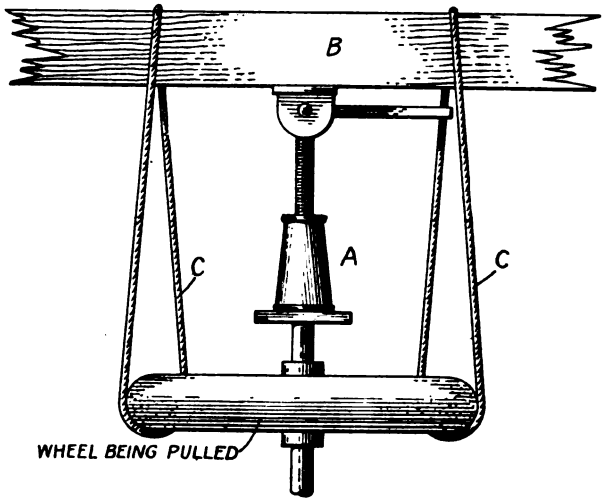
some kind of a clutch brake to be used as occasion requires.

The clutches most commonly used in automobile construction can be subdivided into two distinct types; cone and multiple disk. The single-cone type seems to be most commonly used in small cars on account of the fact that it can be manufactured most cheaply. When properly designed it seems to give universal satisfaction in this type of car. The angle used varies from 9 to 12½ degrees, the latter being preferred. This angle practically eliminates all possibility of trouble in releasing the clutch and with springs inserted under the facing the clutch can be engaged easily without grabbing, and good efficiency maintained. The common practice is to use a good chrome leather or an asbestos fabric for facing. Extreme care should be exercised in selecting the leather. It should be kept pliable by a slight application of neatsfoot oil not too frequently. If asbestos fabric is used, care should be taken in securing a material that is not too hard. It should be carefully and thoroughly carbonized.

A new type of multiple-cone clutch has made its appearance recently. It consists of a series of three small cast iron cones in a single cast iron shell. Light springs are inserted between the cones, a heavy spring actuating the rear cone. When engaging, the forward cone comes into contact with the shell first, then the middle cone, the rear cone being the last to come into contact. When fully applied the three cones form a unit, each doing its own share of the driving. It is claimed that the clutch operates very smoothly. It is, however, still in the experimental stage.

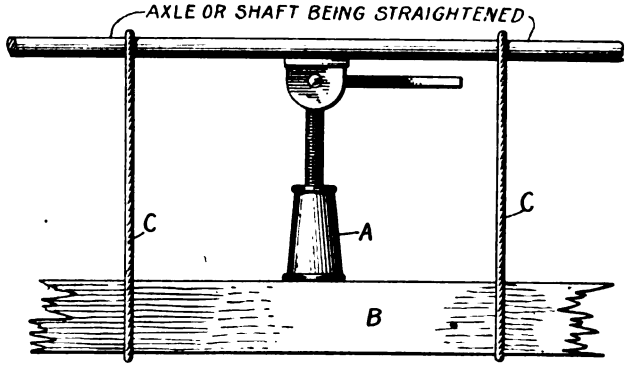
The driving plates of multiple-disk clutches composed of all-metal disks, have in some cases been made of phosphor-bronze, the driven plates being of soft steel, but the best satisfaction seems to be obtained with all steel plates hardened and ground. The clutch is enclosed in an oil-tight housing, oil being necessary to keep the clutch from becoming overheated. The greatest trouble with this type of clutch is to keep it supplied with oil of proper consistency. Good practice is to use a light motor oil cut with a small quantity of kerosene, varying according to weather conditions.

The dry-plate multiple-disk type of clutch is becoming very popular. The driving plates are faced on each side with asbestos fabric, the driven plates being made of steel, generally hardened and ground. Since the efficiency and life of the clutch depends to a large extent on the selection and preparation of the fabric facing, to get the best results the same care must be exercised in preparing it as in the case of the single-cone type of clutch.



In the three-plate type of clutch the facings when used are generally fastened to the single driven plate, although it seems more practicable to fasten them to the driving plates. In this clutch the power factor is obtained mechanically by the use of toggle connections operated by a reasonably light spring. This type of clutch is becoming gradually more popular. It is claimed that some recent designs are very satisfactory.

Warped Valve Stems.



If there is lack of compression and the valve heads seem clean and perfect, examine the valve stems for heat warping.

For Bending or Pulling.

From N. G. Near, New York.—I illustrate herewith how a common jack screw can be used to great advantage by any automobile owner for heavy pulling or bending work. All that is needed in addition to the jack screw is a good stiff beam B (a wooden 6x6 or 8x8 will usually do), and odd lengths of rope or cables C. Since all of these are usually available

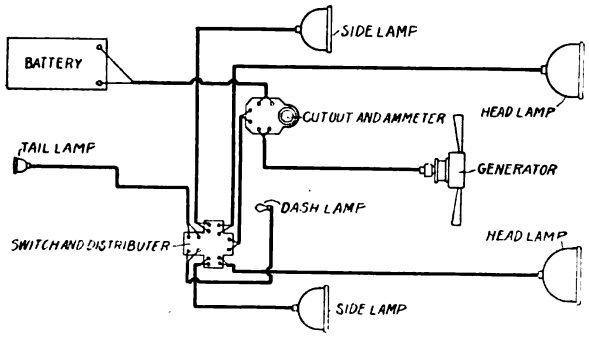
in any small shop, and since owners frequently have them in their private garages, I am calling attention to the good use that can be made of such materials. Even where there is no jack screw, and if you have nothing but ropes, pulling power can be created by use of the old "Spanish Windlass" which will pull off any wheel, and bend any anxle by merely placing

a lever between two ropes and twisting the ropes together, as in the old-fashioned buck saw.

A regular pulling and bending machine is better than the arrangements I show here, I admit, but it would not pay an owner to buy such an outfit for work that he has to do so seldom.

IGNITION CIRCUITS.

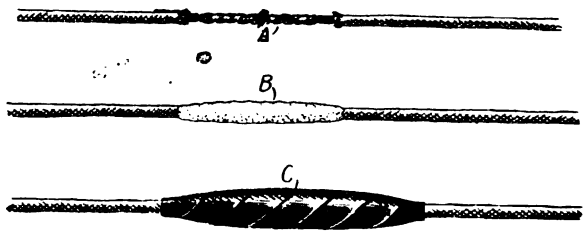
How to Trace and Remedy Frequent Troubles in Connections.



One advantage of the magneto was the elimination of a great deal of wiring and its attendant connections, where trouble could develop. In the days of the coil and accumulator there were very few cars that had the wiring carried out in a manner capable of passing a critical examination, and this is not to be wondered at when the fact is taken into account that the wiring was often left to young apprentices, or, at best, an ordinary chassis fitter, who could not be expected to know anything of the

Digitized by Google

electrical characteristics of good wiring, that is to say, he had to work to rule of thumb. As the magneto simply requires four cables connecting between the plugs and magneto there is little scope for any faulty workmanship other than would result from gross carelessness, such, for example, as running the cables through a metallic tube, and in such a way as to cut through the insulation, instead of taking care that the ends of the tube had well-smoothed bushes of fibre or vulcanite fitted in. It will sometimes be noticed also that the cables touch the top of the cylinders, and unless this is seen to it will cause trouble eventually. Fortunately, engines are not air-cooled, otherwise there would be much more trouble with the insulation than is experienced in such cases. The best of rubber, however, will not indefinitely withstand the heat of a water-cooled engine head. The fault is so easily corrected that it is worth while arranging for the proper clearance between the cable and any heated part. Abrasion of the insulation, due to persistent friction or chafing, even if very slight, is practically the only other fault to be guarded against, so far as ignition cables are concerned.

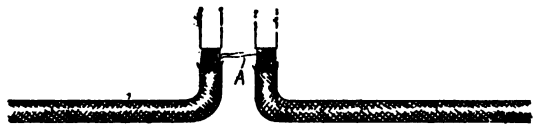


Lighting Installations.

In the case of lighting installations the possibilities for mischief due to minor faults on the wiring are increased. This is one of if not the most serious sources of trouble that the makers of lighting sets have to provide against. Most people are aware what an intolerable nuisance a badly-wired domestic bell circuit can prove, and this is about the simplest electric circuit that can be imagined. A car-lighting circuit is about ten times as complex, and any faults may not only prove to be a nuisance, but may be extremely dangerous to the car user, inasmuch as the light may fail at a critical moment. The leading manufacturers of lighting sets, therefore, take great pains in arranging for the wiring up to be as free from sources of trouble as possible, as shown in the diagram, particularly as regards providing special contacts and terminals, also cable of good quality and heavy enough to carry the maximum load of current without appreciable loss of voltage and consequent reduction of light.

Wiring Diagram for Lights.

Perhaps the most important fact in this question of wiring is that every connection on a circuit is a possible source of inefficiency. Every connection must be made, both mechanically and electrically, as sound as possible. Thus, an unclean, corroded or greasy connection would almost certainly be bad in the electrical sense, even though it may be mechanically good and screwed up well enough to be proof against vibration. On the other hand, a loose contact, even of clean metallic surfaces, would be just as bad. Any faulty connection through which current is passing will nearly always become heated, and this serves as a means of locating a faulty connection. It is an electrical axiom that resistance introduced into a circuit generates heat. Lamp-holders often prove to be sources of trouble in this respect, and nearly always it will be found that it is due to the small spring plungers in the holder being weak and not pressing firmly on the small sectors in the cap of the lamp. Very often it will be found that the lamp gives a bad light, as the result of faulty contact at the plungers. The best remedy is to fit a new lamp-holder.



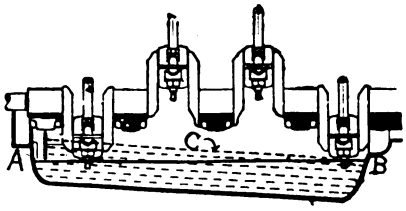
Right and Wrong Way to Connect Wires.

No Joints in Wires.

No properly-wired lighting installation should have joints in the wires, as shown at A. Each length of cable should be complete in itself between terminal and terminal. If circumstances should ever make jointing necessary it is important that the joints should be made in the approved electrical manner and soldered up, as shown at B, with resin as a flux and not with chloride of zinc, despite the fact that it is much quicker and easier to make joints with the latter than with resin. Corrosion of the joint is inevitable sooner or later with chloride of zinc. Proper insulation of any joint is indispensable, and this should be done with the rubber-proofed tape made for the purpose, as shown at C. This is not only necessary to prevent the joint making metallic contact with another wire or any adjacent part of the car, but also to keep moisture from getting into the cable. Owing to the capillary attraction of the fine strands of wire there is a strong tendency for moisture to be absorbed.

Switchboard Connections.

Particular care should be paid to the connecting up at the switchboard, where there are so many terminals in a very limited space. Unless carefully watched in the connecting up odd strands of the cable are liable to touch those of an adjacent cable, as shown at A, or be close together, so that the vibration will cause them to touch at times and produce short circuits, and in some cases cause some of the fuses to break and extinguish the lights. As regards connections to the accumulator terminals, the great faults to guard against are loosening, as the result of vibration, and corrosion. The first could easily be made impossible by the use of a lock nut on each terminal, in fact it is difficult to understand why the accumulator makers do not provide it. Corrosion should never occur on a well-made battery, as the one-time objectionable "creeping" of the acid can be entirely prevented by good



Switch Connections .

Digitized by Google

design. A little of the acid might get splashed out, particularly if more than is necessary to cover the plates is used; therefore, as a safeguard, it is as well to smear vaseline over the terminals.

Overcoming Oil Troubles.

When the symptoms of over lubrication of the first and second cylinders appear, particularly of the former, the owner is inclined to lay the trouble to poorly fitting rings, a worn piston or scored walls. These conditions may exist, but as a rule the trouble is due to the level of the crankcase, as shown by the illustration, which represents an exaggerated case. With the "all loss" system of lubrication, and particularly where the crankcase is not divided or partitioned, the oil will gather at the forward end as indicated. Under this condition the level is not normal as represented by the line A B. As may be noted the spoon of the connecting rod of the first cylinder is dipping too deeply, and the result is that an excess amount of lubricant is splashed to the cylinder walls, flooding them. A portion of the oil is bound to find its way past the rings, depositing an excess amount of lubricant in the combustion chamber where it burns, forming carbon, and fouling the plugs.

Note the Oil Level.

The cause is generally due to the front springs settling, and half an inch will make considerable difference to the motor lubricated by the straight splash system. The remedy is to level up the crankcase. It is a simple matter to measure the height of the lubricant. Drain off the old oil and wash the case thoroughly with kerosene or gasoline. Next use a colored fluid, such as an ordinary dye employed for dyeing cloth. Use the same amount of fluid as you would oil, but do not crank the motor to splash it. Remove fluid and crankcase, and the height will be noted as well as how deep the rods dip by the color. Measure to ascertain how much the level is out, and block up with pads the springs to that amount. This remedy is more satisfactory than the fitting of baffle plates or drilling the pistons. The straightening or blocking up of the springs will improve the riding qualities of the car as well.

AUTOMOBILE WELDING.

Expansion and Contraction of Metals in Using the Oxy-Acetylene Flame.

BY M. KEITH DUNHAM, OXY-ACETYLENE ENGINEER.

One of the very difficult points to drive home to the automobile mechanic, in the application of oxy-acetylene welding, is the power of expansion and contraction. A shaft is out of true, a pair of cylinders won't fit the stud bolts of the case after the lugs have been welded, a lower half of a crank case does not line up with the upper half, the welding is all right but the effects of welding have been overlooked and provision has not been made to offset or overcome the shrinkage caused by the cooling weld.

A pattern for a casting is always made oversize "to allow for shrinkage." When the foundryman pours the metal into the mould he knows, and so does every mechanic, that as the metal cools, it contracts and when cold it is shorter, not so wide and not so thick as it was when it was poured.

Nothing can prevent the contraction or shrinking of cooling metals.

Oxy-acetylene welding is a fusion process—not soldering or brazing. The metal to be joined is melted; so that if we consider the process merely a re-casting, locally applied, it is easy to understand the futility of putting shafts in bearings of crank cases or bolting angle irons to the sides to prevent contraction.

Some apparatus manufacturers with more theory than practice recommend such devices—their use not only does not prevent contraction but their weight on aluminum may be a positive danger when the casting becomes sufficiently hot from preheating, in crushing or collapsing the heated area. If we heat metal, we must expand it and it must occupy a smaller space cold than hot—therefore, if we bolt the case to an angle iron in cooling either the angle iron will bend or the casting will crack. If we preheat the case with the angle irons or shafts firmly attached to the case we again get into difficulties for aluminum and iron have a different ratio of expansion and we are very likely to break the case by reason of the angle iron or shaft not expanding as fast as does the aluminum.

When a case is broken into many pieces, it may sometimes be deemed advisable to use angle irons and shafts in order to secure alignment. Take these off before welding, however, as their use is really a detriment—they lead you to believe that they will prevent contraction. As well try to dam Niagara.

How then prevent distortion or warping of the article welded or contraction cracks? In some cases it may be done by bending, by limiting the heated area by the use of wet cloths or asbestos or in the case of sheet metal welding by opening one end of the weld a certain percentage of the length of the weld.

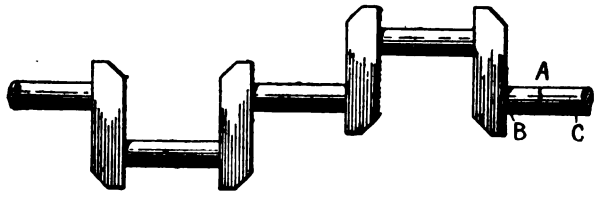


Fig. 1.

The best way and the one which must be applied in nearly all cases of automobile repairing is to offset the contraction of the welded area by preheating another section or in some cases by slowly heating the whole article.

Preheating, however, is not necessary on all kinds of automobile repairing but is absolutely essential in many instances. Three things must be taken into consideration in judging whether an article must be preheated to overcome the effects of contraction, first, whether there is an opportunity for the expansion and contraction to take place naturally; second, the conductivity of the metal welded, and third, the ductility of the metal.

Take a crank shaft as an example of the first in-

Digitized by Google

stance, as in Fig. 1. Here the weld is made at A. The distance from B to C will increase as the metal becomes hot and decrease as it becomes cold. The end, C, being free, there is nothing to prevent its moving and it does so. No preheating in this instance is necessary therefore to offset contraction, though it is helpful in saving gas and in keeping the metal in proper fusion. A weld in the chassis, a lug or an arm on an aluminum casing, a truss or torsion rod or tube, are further illustrations of this character.

Take a break in a water jacket of an automobile cylinder, roughly outlined in Fig. 2, A to A. If we weld this break, as we would the shaft in Fig. 1, how about the contraction? The jacket is one solid piece and is firmly joined to the cylinder in many places. Furthermore, cast iron is not ductile and will not bend readily. The welded section must cool and in cooling in must occupy a smaller space than the molten metal. It being impossible for the metal to shrink along the general lines, B to B, and cast iron being brittle (not ductile) the weld being the weakest section (because it is hot) breaks. If the jacket were steel, which is a ductile metal, it would be possible to make the weld without contraction

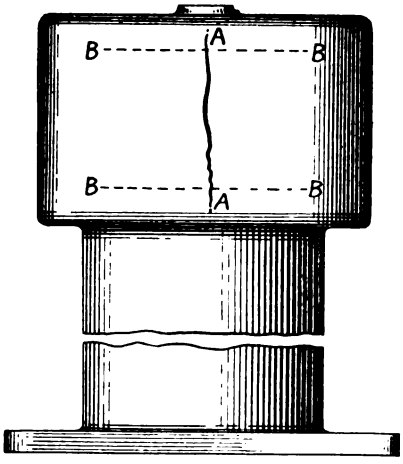

Fig. 2.

breaking the weld for the reason that other portions of the jacket would twist or warp and so take care of the contraction.

But if we take the cylinder and warm it all over to a dull red heat, we expand all portions of it, the weld is quickly made and the cylinder being practically the same heat everywhere it cools and contracts equally everywhere.

The same condition holds true in an aluminum casting but in this instance contraction breaks are not always the case, as this metal will many times twist or warp out of shape instead of breaking. Aluminum is an excellent conductor of heat, therefore the expansion set up by the welding flame is a considerable one and the shrinkage in cooling is correspondingly more than in other metals used in automobile construction. Cast iron will usually break in cooling unless allowance is made for this contraction by preheating. Aluminum, on the other hand, may bend other sections in cooling, due to its ductility, and this is the reason why at times after welding a case will be found to be shorter on the welded side. The welder has "taken a chance and welded it cold." The weld held but the case was useless because it was not in alignment.

One-half of a malleable rear housing is brazed and when assembled it leaks grease badly. Because it didn't break in cooling (malleable iron being ductile) the job is considered successful. If the housing was preheated carefully the machined surfaces would have properly fitted together.

Each repair job is of course different. Each has to be studied but if the law of expansion and contraction is recognized and you have a full understanding that you cannot prevent contraction by clamps but that you can offset it by preheating and careful cooling, you are on the way to becoming a successful repairer by the oxy-acetylene process.

TROUBLE-DEPARTMENT

This department is intended as a "trouble clearing house" for car owners, dealers and repairmen. Inquiries in relation to marine motors will likewise be answered as they are of interest to car owners and others who use the two-stroke cycle engine.

Readers are requested to make criticism and comments or to freely discuss any subject of interest to the automobile industry, and to add information of their own experience in remedying troubles.

Inquirers are asked to give the fullest information in every case so that replies may be made intelligently, and thus be of interest not only to the inquirer but to others.

1648 E. M. F. Valve Timing.

From W. S. Haines, New Jersey.—My car is an E. M. F. 1912. When adjusting the valve stems and timing same, should they be adjusted when the piston is at the top of the cylinder? If so, they make quite a clatter, but if adjusted while running, then the valves leak from not seating properly.

Reply.—The inlet valves ought to open in time to give the pistons a chance to draw in a cylinder full of gas. The practice is to allow the piston to descend about 1/8 of an inch in the cylinder before the inlet valve opens. This reduces the pressure and creates a suction. The inlet valve should close just after the piston has reached the bottom of the stroke or about the time it has traveled a half inch up on the compression stroke. The exact point at which the inlet valve should close depends something upon the speed of the engine, but whatever setting is arranged it will not be quite suitable for all the speeds of the engine. The usual practice, however, is to set the valves according to the average speed of the engine, or about 1,000 revolutions per minute. As to the exhaust valves they must open before the piston reaches the end of the explosion stroke, or about a half an inch from the bottom of the dead center. Different manufacturers give slightly varying instructions as to valve timing and it would be well if you could get the instruction book of the E. M. F. Company, or what is now the Studebaker Corporation, at Detroit, Mich.

1649 Trouble With a Lozier.

From C. N. Osborn, New Jersey.—I drive a 1913 six cylinder Lozier car. It has a Rayfield carburetor, model D 4 X, size 1½ in. 1.—Motor seems very sluggish at starting, sometimes on the road, especially on up grades. Will not "pick up" as it

Digitized by Google

should. In damp weather the motor runs decidedly smoother. Have tried various carburetor adjustments, but don't get results. Float in carburetor allows chamber to fill about one-third with motor running idle about 12 M.P.H. 2.—When going down grade—throttle closed, switch on—there is a noise, similar to a strong puff of air (not an explosion), that comes from the muffler at short intervals—not regular. What might cause this? 3.—Carburetor has large water jacket between "butterfly" valve and base of intake manifold, besides the regular water jacket, both connected by pipe line. Could I safely connect the upper jacket to the exhaust manifold and run a pipe from the lower one out under the motor or back into the exhaust manifold back from the motor? Would this make the gasoline too hot? 4.—Spark plugs now used extend only half way to bottom edge of valve caps. Would using longer plugs improve running or power of motor? Could the two plug system increase the power of the explosions to such an extent as to injure the bearings? 5.—Could worn valve lifter parts affect the lift of valves enough to interfere with the proper intake and exhaust of the gases? 6.—Have trouble in getting my brakes (internal expansion) to hold. Can tighten same so that wheels bind and yet car will slip with a hard pressure on pedal. All linings are almost new. On inside of drum is a slight groove caused by wear. Could it be the edges of the grooves prevent the whole surface from touching. 7.—Have you ever had inquiries regarding a mysterious metallic grind in this make of car? The noise seems to come from the vicinity of the clutch or transmission only when the engine is under load with the car in motion. When coasting with the clutch out the noise is not heard. At the New York Service Station I was told the trouble was with the clutch. A new one was put in and the same noise was worse than before. I have had the transmission apart, examined every gear and bushing, all of which were in excellent shape, and am satisfied the noise is not there. Would worn or loosely meshed "spider" gears in the differential, with the vibration of the drive shaft, make such a grind?

Reply.—Your car is probably the Lozier "Big Six," a few only of which were put out. 1.—You will probably find that a more modern carburetor will give you better results than the D 4 X. 2.—Puffs are probably due to infrequent explosions of a weak mixture of gas. 3.—If you desire, although it would probably make little difference. It would not make the gas too hot. 4.—Probably, although they might foul more easily. Bearings would stand considerable more power. Some of this model car were equipped with two-point ignition, but chauffeurs rarely employed it except for high speed work, on account of tendency to pound from too rapid combustion when running at low engine speed. 5.—Possibly, but hardly probable. 6.—Brakes on this car are inadequate, hard to adjust and need almost constant attention. Braking surface is small. 7.—We have never before, so far as our recollection serves us, had any inquiry concerning this model car. Information here given is following two years observation of the car in almost daily use.

1650 **Certain Assumptions.**

From J. B. C., Massachusetts.—1—When an automobile weighing 4,000 pounds or more, requires a gallon of gasoline to run from 7 to 8½ miles, a car weighing less than 3,000 pounds should go from 8 to 9½ miles per gallon. Ford cars should go from 15 to 25 miles per gallon of gasoline. What is your opinion? 2—A car going at the rate of 15 to 20 miles per hour requires less gasoline than when going at a speed of 30 miles per hour. If a car will go a certain distance on 7 gallons of gasoline at a speed of 30 miles per hour, at a speed of 20 miles per hour it should run one or two miles more on a gallon. What do you say? 3—Does a four cylinder motor require less gas than a six or eight cylinder motor, used in the same car?

Reply.—1—The tendency is about as you claim but the results would probably vary widely. A good many other things besides weight must be taken into consideration in making estimates of this sort. 2—The amount of gasoline consumed depends a good deal upon the speed, the car, and upon other facts in relation to driving, but the difference would vary so much under different conditions that it is not possible to estimate by figures, except approximately. 3—Other things being equal, a four cylinder car uses somewhat less gasoline than a smaller car having six or eight cylinders. Tests have been made, however, where a greater number of cylinders have run with even a less amount of gasoline than the less number. In all of the foregoing assertions or inquiries the tendency may be about as stated but the facts are altogether uncertain.

1651 **Wiring for House Light.**

From Lee Bugg, Arkansas.—I want to fix up a strip of lamp sockets like diagram enclosed to take 60 volts off a 110 volt arc line. Can you tell me how much voltage each 32 c.p. lamp will carry? The current comes into my house at 110 volts and I have an arc light that consumes only 40 to 60 volts. The rest of the current is disposed of through a resistance rheostat at present. This rheostat gets red hot and of course is very uncomfortable in the house these hot days, besides I think this arrangement consumes more current than it should.

Reply.—Your plan is impracticable. You might use two arc lamps in series, in which case the strength of the current would be approximately 55 volts to each lamp. You can put in an oil transformer, but in either case the expense would be considerable. Incandescent and arc lamps do not work well in the same circuit in series, but are often placed in parallel, in which case they all take the current at the same strength or voltage. This latter arrangement would not help you in the least. Arranging lamps as per your sketch, which is in parallel, would not decrease the voltage but would increase the amperage, taking a greater quantity of electrical energy at the same pressure or voltage. Thirty-two candle power carbon lamps consume about 100 watts of current per hour. The product of the volts by the amperes is the number of watts. Thus: 110 volts at 5 amperes per hour would be 550 watts, or watt-hours, and 55 volts at 10 ampere hours would also be 550 watts.

1652 **Faulty Lubrication and a Short Circuit.**

From L. C. H., Vermont.—I have a model 37, 1915, Buick, which has been driven less than a thousand miles and has given good satisfaction, except the following: For lubrication the directions are to "remove the wing plug on the right side of the timing gear case of the motor, and fill with motor

Digitized by Google

oil. This is for the pump and generator shaft." If this is done a part of the oil leaks out into the pan and the greater part into the crank case. The motor begins at once to smoke badly and the only way to stop that seems to be to draw nearly a gallon of oil from the petcock. 1—Should the packing around the crank shaft be replaced? 2—Is this difficult? 3—Would supplying the necessary oil to the crankcase through the oiling place mentioned, insure a sufficient amount of oil for the pump and generator, shaft, gears, etc., and would it be advisable? The ignition system is the Delco. In one instance, without any cause which I have been able to determine, the motor while running on a level, suddenly ceased firing and a loud cracking noise called my attention to the switch which I found to be heated. Pulling out or pushing in the "M" or "B" button made no difference, the motor would not fire or the loud cracking sound stop. After a little I found, without knowing just how I did it, that I could stop the sound with my fingers underneath the combination switch, but that it would begin again when I removed my fingers. In this way, trying to locate the cause of the short circuit, it stopped as suddenly as it began and has not troubled me since. I would like to know the cause of this short circuit and how to prevent it in the future.

Reply.—1—Looks as if the forward crank shaft bearing were defective. We do not know of any design of engine using packing to prevent leaking of oil from the timing gear housing to the crankcase. 2—To put in new bearings is rather expensive. 3—Probably not. 4—The short circuit was probably in the timer, where the contact was made and did not break. Careful examination of the timing head may explain the short circuit.

1653 **Defective Ignition.**

From H. E. Mitchell, Colorado.—Would you tell me what is the matter with a Case car, model 1910, Remy low tension magneto, Stromberg carburetor, type B? We do not seem to be able to get the spark past the distributor. We have a new set of batteries, and by taking the high tension wire from the distributor plate and pushing the push button we can get a spark nearly an inch long, but on starting the engine it will run a few turns and quit sparking at the plugs. As we have "sparklets" on the plugs we can see when it sparks. The platinum points are in good condition, one of them being new, and they break about one-sixteenth of an inch. The engine is O. K. in other respects and the carburetor is adjusted according to the Stromberg instructions.

Reply.—Trying to see how long a spark you can "pull," according to your confession, in itself is sufficient to ruin any jump spark coil. Your coil probably has a perforated condenser or a broken down secondary wiring. Our advice is that you send the magneto and coil to the nearest Remy service station, providing, of course, the engine itself has sufficient value to warrant this expense, and that a more modern design of carburetor be purchased. You must remember that the engine is some six years old, and that it may need expensive overhauling. One-sixteenth of an inch seems like a wide setting of the contact points. It is barely possible that the gaps in the "sparklets" are too wide, or the plug gaps themselves may be excessive. There are several conditions that may be present, any one of which may give ignition trouble such as you describe.

1654 **Missed Explosions.**

From Foresman & Lowe, Indiana.—We are operating an automobile garage and have 5 Maxwell Special cars that we are having a time with. We seem to have too much resistance at the spark points. I have stood and watched the spark from the top of the plug to the steel shell, a distance of an inch. These cars use Splitdorf coils and they will only last about a year. Setting the points as close together as it will hit has no effect. At times the spark will jump from one point to the other on the magneto rather than go to the right plug. We have tried all kinds of plugs, but they all seem to give out in a short time. The missing is worse after the engine has stood for a while or when started up in the morning. The plugs "foul" very easily. The engines do not seem to get too much oil, as they do not smoke any more than any other car does. Can this be oil or compression trouble? And what would you suggest as a remedy. We have trouble in keeping the sparks from coming through the cables. It will come through a new Packard cable at these missing times.

Reply.—It seems to us that for very best information the Splitdorf Electrical Co., Newark, N. J., or the manufacturers of these cars, should have been consulted. The jumping of the current does not do any harm so long as it does not cause ignition failure. The "fouling" of the plugs may be due to impaired compression, faulty lubrication, worn piston rings, or it may be a result of missed explosions. It is possible that a slightly thicker oil may help you. We think that a personal letter to Dr. R. H. Cunningham, care Splitdorf Electrical Co., Newark, N. J., setting forth conditions as you have described them to us, will result in a helpful reply to you.

1655 **Road Rules.**

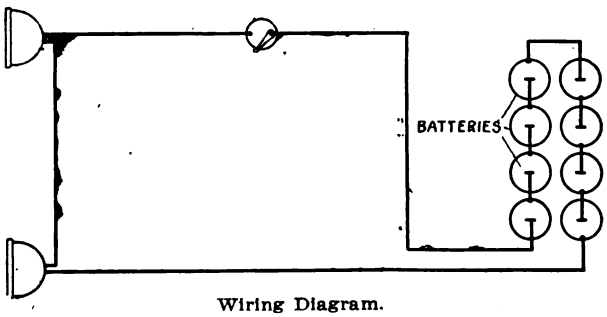
From R. E. Shepard, Iowa.—1—I wish you would print a column in your paper about the road law. There are people everywhere, I believe, who do not know what side they are to travel on. 2—Is the fourth speed on a car very valuable or not? 3—On an average do you think it pays to buy non-skid tires? 4—How is the constant level splash oil system kept to a certain level? Is it done by float or how? 5—About how many automobile manufacturers are there in the United States?

Reply.—1—The rules of the road are very simple indeed, and should be known and followed by every driver of horse drawn, as well as motor driven vehicles. The trouble is not so much because of not knowing as in not caring. 2—It must be, else motor car manufacturers would not use four speeds ahead and a reverse when three ahead would be ample. 3—Without any doubt. 4—Usually by a tube extending a short distance into the crankcase compartments, connecting with the pump, or reservoir beneath, to drain off the excess. 5—Between two and three hundred, and the number is constantly varying.

1656 **Uses Ford Engine in a Motor Boat.**

From A. J. Applegate, Kansas.—I enclose you a clipping taken from a recent number of the Automobile Dealer and Repairer, and as I know that you would not willingly create a wrong impression to any subscriber asking a question, I wish to state that you have wrongfully answered this gentleman.

Digitized by Google



I have been using a Model-N, four-cylinder Ford automobile engine in my boat for several years with perfect success. It controls readily, cranks easily and certainly, and in my judgment is far superior to the two-port engine that is usually installed in motor boats. I will be glad to answer any questions about this that you or your customers may desire, and would like for you to print the letter.

Reply.—Of course we know absolutely nothing of your boat, its design, construction or to what use it is put. We do not know whether this is your first motor boat experience or you have been shipmate with "real" marine engines. It is not that we would discourage any one who can afford to make a manifestly improper application of power to boats, from experimenting such as you have, but to dissuade those who perhaps can ill afford to waste their time and money. Again we reiterate that "Our advice is not to even consider using a Ford or any other automobile engine for a boat," fully believing, in spite of your installation, that our contention is justified in the premises. The writer of this reply has had some twenty or more years of practical marine gas engine experience, and is considered an authority in matters pertaining to this application of the internal combustion engine, and has observed hundreds of marine installations, as well as scores of unsatisfactory attempts to utilize used motor car engines for marine use. Every such one being unsuited to motor boat use.

1657 Lamps Lighted from the Battery.

From Edward Snyder, Pennsylvania.—I have two lamps which run with a dry battery, and would like to know if I have them wired up right to give the best light. Send me rough sketch and what voltage, bulbs and candlepower to use to give the best light.

Reply.—Use eight cells which will give you about twelve volts, sufficient to light two 6-volt lamps in

Wiring Diagram.

series. Instead of "grounding" the pole of one lamp and one side of the battery to the frame of the car, run a wire from the lamp to the battery so there will be a complete circuit without using the frame. The lower the candlepower the lamps are the longer the battery will last. You will find it expensive illumination.

1658 For Keeping Gasoline.

From Reader.—I have a bill from the Fire Department of the City of New York for the privilege of keeping gasoline in my car in my private garage. Will you kindly let me know whether this is a proper charge and should I pay same. I understand that the Automobile Club of America or some other such club says that it is not a just tax and have instructed its members not to pay same.

Reply.—The keeping of explosives is prohibited by the ordinances of the City of New York and it follows therefore that if the city officials wish to enforce this ordinance against you that they could prevent you from keeping the gasoline in your garage. I should think that the wisest and cheapest thing for you to do would be to pay the bill, provided, of course, the bill is not an exorbitant one. If you refused to pay the bill and the city officials acted arbitrarily in the matter, the ensuing trouble and annoyance would cost you many times the amount of the bill. If the Automobile Club maintains that the tax is unjust, it is up to them to fight the case in the courts, but I hardly think it worth while for you to shoulder the burden of establishing that fact. If you are a member of the Automobile Club, it would be well for you to notify them of your case so that if they determine to make a stand against the tax, they should include your case along with the others now under their observation.

1659 Wiring for Lights.

From Edgar Norris, Indiana.—I would like to know whether it is possible to wire a Ford, 1915, touring car, with a system whereby I can use the

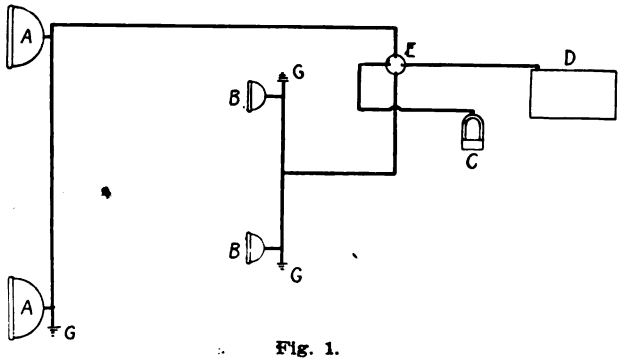


Fig. 1.

magneto and storage battery for lights. The idea being to shift my light in town to the magneto and in the country to the storage. It would save my battery some and also comply with the dimming ordinance, as one does not get enough light from a Ford magneto to blind anyone, except when in neutral and speeding the motor. I have asked several good electrical repairmen about it and they say it can be done, but cannot tell me how to do it, nor what kind of a switch to use.

Reply.—Remembering that the current produced by the Ford magneto is approximately of 12-volt

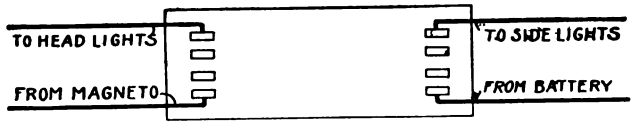

Fig 2.

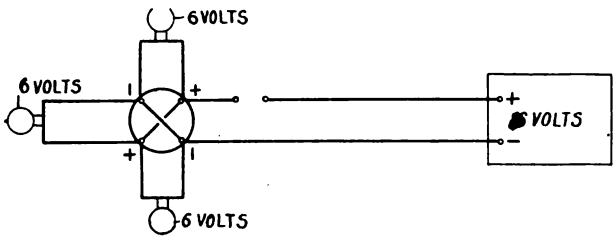
strength, and that the three-cell storage battery is 6-volt, in order to use either source of current supply at will it would be necessary to have a rather complicated system of series and parallel wiring, except you were to wire your headlights for magneto current, connecting them in series so as to use 6-volt lamps and then wire your side lights in parallel with your storage battery, using also 6-volt lamps. The diagram accompanying this reply, Fig. 1, should be sufficiently clear for your understanding. AA represent the head lights, BB the side lights, C the magneto, D the battery, E the switch and GGG lamp grounds. The switch is a circular affair with



Digitized by Google

four contacts and a lever which may be made to connect opposite contacts. If desired a double pole double throw switch might be adapted for use by making a metallic contact between the two arms, as in Fig. 2, a strip of soft copper being fastened under the insulated crosspiece to which the handle is fastened.

1660 **For a Dash Light.**

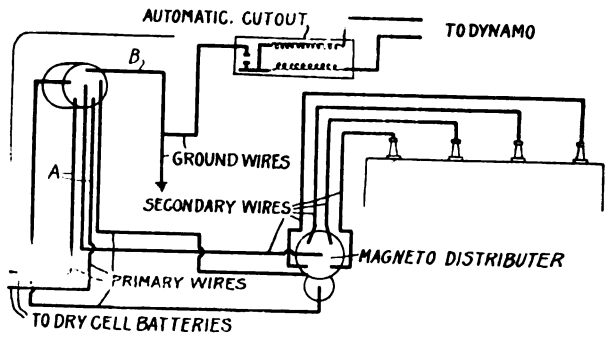
From C. F. Abbott, Maine.—As I am a subscriber to your valuable paper, I would like to ask you a question. I would like to put an electric light on my dash near the coil and take the current from the magneto. Will you send me a diagram of wiring and how and tell me how great a candlepower to use? My car is a 1914 Ford. Do you know of any company that sells this equipment?

Reply.—You can purchase from almost any electrical supply house or from garage stores, such an outfit as you describe. All you will need to do will be to run a wire from the one which connects the binding post on top of the magneto to a small switch, another wire from the other pole of the switch to one binding post of a small 12-volt lamp and connect the other pole of the lamp to the metal frame of the chassis or some part of the motor. If you can-

Electric Light Diagram.

not purchase small 12-volt lamps use two 6-volt lamps in series, running the current through both lamps and "grounding" the second one. If you connect the two lamps in parallel you will burn them out.

1661 **Magneto Bearings.**



From John A. Kelley, California.—1—Can magneto armature ball bearings be reground? 2—Is there any way to take up wear in magneto armature ball bearings?

Reply.—1—The ball bearing races can be reground providing the proper appliances are at hand, such as are used in their manufacture, but it will necessitate using new and larger balls. New complete ball bearings are not expensive and can be purchased at almost any supply house. The number and letter on the bearing is standard for size among all ball bearing manufacturers. 2—No.

1662 **Starting Ignition.**

From George K. Weller, Michigan.—I have a model 79 Overland equipped with Gray & Davis starting and lighting devices, Willard storage battery, one wire or grounded system of wiring. Ignition is by Splitdorf magneto and coil, using dry cells for ignition in starting. Can I successfully attach my storage battery to the coil to replace the dry cells? I understand that in some systems using dry cells it is necessary to connect one of the wires to engine or car frame, or in other words "ground" one side of dry cell circuit, but on this car both wires from cells lead to coil and then the coil is "grounded" to engine. Would I "short" my battery in trying to use it for starting ignition? If possible kindly give wiring instructions. I suppose my inquiry should have been sent to the Splitdorf Company but it seems that it would be of general interest to discuss through your journal.

Reply.—If it were possible to dispense with the battery of dry cells, you may rest assured the Willys-Overland Company would do so. The only reason they furnish a battery of dry cells for this purpose is because it is cheaper than a separate 6 volt storage battery would be. When the starting battery switch is closed to operate the starting

Mr. Weller's Diagram.

motor, current can only be drawn from this battery for the purpose of starting. It would be an extremely simple matter to operate the engine, using the starting battery for ignition, after it is once started, but one cannot start and furnish current for ignition from the same storage battery. Grounding on the engine itself results in less resistance in the circuit than grounding one pole of the battery to the chassis frame. A hotter spark would be obtained if both electrodes of the spark plug were insulated and instead of grounding on the engine base the circuit could be completed without grounding at all. In your car one wire leads to the coil while the other leads to the switch. The opposite pole of the coil is connected to the magneto make-and-break mechanism. If both poles of the battery were to be directly connected with the primary winding terminals of the coil you would have a dead short circuit, and your batteries would last but a few minutes. You had better look your wiring over again and make a diagram of it, when you should be able to understand why both leads from the battery could not be connected to the primary winding coil terminals.

(SECOND LETTER.)

From George K. Weller, Michigan.—I shouldn't care to edit the "Trouble Department." When a fool question were asked I might be tempted to squelch the asker and incidentally make interesting reading for subscribers. In my case, if my question seemed foolish to you, I can assure you that I had given the matter considerable thought before writing you, and although you say that it would be a simple matter to use my storage battery for ignition after getting started, I fail to see how to do the wiring. The circuit from my battery to lights, horn, etc., is through positive wire to starting motor. The same terminal connects to the chassis frame, forming a circuit through the frame to the lights, through lamps, lamp wires to the switch, to the negative wire and back to the battery. These circuits,

Digitized by Google

or the direction in which they flow, is reversed when the dynamo is charging. Now in some cases where dry cells are used for starting ignition, one pole of dry cells is connected to "ground" and the other to the switch. The circuit is through the switch to the coil, to the H. T. wire, to the spark gap, across the spark gap to the ground and grounded wire back to the dry cells. While in my case (as I see it) the circuit is through one of the wires (marked "A" in diagram) through the switch to the coil, to the H. T. wire, to the distributor, to spark plug gap, across the gap to ground, through ground wire "B" to a circuit, through the coil to the opposite "A" wire, back to the dry cells. If I have "doped" it right I can see no way to utilize storage battery current for ignition. If you can, and you did say so, will you kindly publish a diagram showing how it can be done.

Reply.—If you carefully read our reply you will note that we said it would be a simple matter to use storage battery current from the starting battery for ignition while this battery is not being used for starting purposes. You would simply connect the storage battery, by means of an independent switch, or a two way switch which would control both the dry and storage battery, in parallel with your lights, etc., and also in parallel with the dry battery. We do not advise it, however. It does not matter in which direction the current flows. The circuit, by which we infer that you mean the primary circuit, is not through the high tension wire nor to the distributor, the current flowing through these two elements being the induced or secondary current which in its circuit usually passes over a part of the primary circuit, and may be in the opposite direction at that. One of the battery wires is "grounded" when the switch is in battery position, completing the circuit through the make-and-break mechanism. If you were to use your storage battery for ignition you would have to put in an additional switch to perform the function now performed by the switch when using the battery of dry cells. We will not publish such a diagram as you request for we think by refusing to do so we will save some of our readers a lot of trouble, in case they were to attempt such a stunt as you apparently contemplate. Our advice to you is to forget entirely what we said in this connection and let well enough alone, unless you are prepared to replace your expensive storage battery, in case you should not make the connection correctly.

Remedy for Knocks and Thumps.

From Frank F. Casseday, California.—I see that several of your correspondents complain of knocks and thumps in their autos, and are unable to remedy or locate the trouble. Make a practice of washing out the radiator once a month with a hot soda solution. Drain all the water out of radiator. Put a large handful of common house soda to a ten-quart pailful of boiling hot water. Shut the drain cock and fill the radiator system full of this hot soda water. Turn your engine over a few times while the soda solution is in radiator. Empty and fill again and repeat until two pailfuls of the hot soda solution have been put through the system. Then drain the soda solution all out, and fill with clean cold water. You will be delighted with the effect on engine. The outside of cylinders become coated with rust and dirt and the soda solution cleans it off. This coating stops the radiation of heat and consequently the engine overheats, and trouble results. A similar condition is seen in steam radiators in buildings used for heating. Certain kinds of paint cut down heat radiation so much that their use is contra-indicated. If your auto is run up hill and down and is doing lots of work drain and wash out radiator system twice a month. The machine will do better work, will run easier and will make more mileage on less oil and gasoline.

For Starting the Ford.

From Dr. F. F. Casseday, Oregon.—Several of your correspondents have complained about inability to start their Ford cars after running for some time and standing from 15 to 20 minutes. I had some trouble on that score. The Ford plant here looked the car over carefully, but could not find cause. I have come to the conclusion that some gasoline engines should have a good supply of explosive gas in the cylinders when the engine is stopped after running for some time. It is my custom now before killing engine to open gas throttle wide and then shut off magneto. If in spite of this precaution the engine balks, turn the carburetor to right and shut off gas. Either or both of these will start the engine. After engine starts put carburetor back to place where it usually works when engine is running. Some drivers say they leave the carburetor in the same place all the time. That seems an impossible thing to me, for as weather conditions change from hot to cold less gas and more air, or vice versa, are necessary. Again when climbing hills, advance the spark until there is a knock, and drivers will be surprised and delighted how the Ford or any other car will climb hills on the high, and how little gasoline is used for road work and hills. It is no uncommon thing for me to get from 25 to 30 miles on a gallon of gasoline with my Ford, but to do this it is necessary to give the engine a good fat spark. The fat spark and free ignition burns up the gasoline clean, gets the maximum of power out of it, and keeps your cylinders clean of carbon.

Road Pigs.

From N. G. Near, New York.—While motoring with a friend the other day it was forcibly brought to my attention that there is a vast difference in the demeanor of our co-motorers, especially in the matter of turning out of the road enough to give a driver who is in a hurry an opportunity to pass.

My friend was anxious to make a town in New Jersey by a specified time and was therefore in a greater hurry than were the car drivers ahead. However, we weren't going fast. Ahead of us, in a certain length of road where there was room enough for two cars to comfortably pass there were six automobiles, all going in our direction. My friend "gave each the horn" and the five first drivers immediately turned out enough to allow us to pass. There was no hesitation whatever on their part about giving us what we wanted.

The sixth and last man, though, was differently constituted. He had several young ladies with him and evidently thought it was "smart" to block the path. Every time my friend sounded the horn I could see the front wheels swerve slightly "toward" the side on which we wanted to pass. My friend tried the other side then, sounded the horn again, and again the car ahead swung directly into our front. The ladies turned back and giggled, for, I suppose, they were just out for a pleasure ride any-

Digitized by Google

way. After several miles this car turned and took a direction different from ours and we had no more trouble, but the incident created a most unpleasant feeling in all of us anyway. I am sure the conscience of the driver ahead must have troubled him.

The gravest danger in playing this game is the "madness" of the driver behind who wants to pass. I know of instances where he has lost entire control of his good sense and has crashed into the rear of the blocking car only to admit later that he did the wrong thing and voluntarily paid for the ruination of both cars. The blocking driver also usually admits that he was in the wrong, that he should have turned out, and thereafter views the subject from the more ethical standpoint.

My object in writing this, therefore, is to point out the fallacy of hogging the road, especially on a road where there is no dust, where there is plenty of room, and where you are traveling at a comparatively slow rate. Keep your head at all times. The best rule I know of, applicable to this case, is the old Bible verse, "Do unto others as you would have them do unto you."

Coasting and Compression.

From J. J. Gloudemans, Wisconsin.—Regarding the coasting test of N. G. Near which has been so vehemently criticized by F. L. Angier, I wish to state as my opinion that Mr. Near is right. Other things being equal, a motor with good compression will coast further than one with poor compression. The reason is very simple: The compression in one cylinder is fully neutralized by the simultaneous release of compression in another cylinder. These two forces counterbalancing each other, we may say that under good compression the engine runs idle, as far as the compression and release strokes are concerned, whilst under poor compression there is a continual air friction. This also applies to a one or a two-cylinder engine, because at the proper velocity the release immediately succeeding the compression in the same cylinder will act as a neutralizing force. In other words, whatever amount of power is necessary to push a piston up against the compression that same amount of power will be a help in pushing the piston down on its downward stroke, whilst the momentum of the flywheel or rather of the car itself will take care of even running.

Woodworth Leather Treads.

From Paul L. Maltbie, New York.—I wish to give you my experience in relation to the benefits derived in using Woodworth leather treads on my tires. I have read in your paper that some autoists are skeptical as to their use. Now I have a Buick, model B 25 car, which I purchased October 23, 1913, and I put the Woodworth treads on all four tires at that time. I have run the car over 4000 miles on brick, macadam and dirt roads, through ice, snow and mud. During the length of this period of time I have never had a blowout or a flat tire. I have never had any occasion to bother with my tires, only to keep them pumped up to a proper pressure, 70 pounds. It is a pleasure to motor when you feel confident that you are not going to have tire trouble. I would not drive my car without these treads. There is scarcely a time that I am driving along the road but that I meet one or more cars by the roadside, who are busy repairing a puncture or a blowout. I think to myself, when I see them, if they only had these treads they might be on the road rejoicing. I have never seen my inner tubes. I do not know if they are grey or red rubber. The rubber shoes are in perfect condition, like new at the present time. I have recently put on a new set of treads and expect to get over 10,000 miles wear from my tires. When I replaced the new treads, it offered me an opportunity to examine my rubber shoes, and I found them to be in perfect condition, as aforesaid. I find it much more economical to buy the treads than to buy new tires and new tubes destroyed by blowouts.

Gasoline Fume Dangers.

From Dr. Lester Curtis, Illinois.—It may interest you to know that from the four or five friends with whom I have talked since they read the article on auto-gas poisoning in your June number, I have heard reports of three fresh cases of the poisoning. Two of these were told me by trustworthy people and were probably true, but they were second-hand stories and I was unable to get the details of them.

I learned of the third case from the patient himself. He is a prominent business man, experienced with machinery and drives his own gas car. While busy one day in his garage he suddenly noticed that he was feeling unaccountably drowsy and weak. It occurred to him that he was suffering from gas poisoning. By this time he had become so weak that all he could do was to drop to the floor and with difficulty roll to the door. He was unable to turn the lock, but fortunately found a crack into which he pressed his face. After a time the fresh air revived him sufficiently to enable him to get the door open and escape from the garage.

The quick and insidious working of the poison is noticeable; the man's life was hanging by a thread before he suspected anything wrong. A little hesitation and loss of time would undoubtedly have been fatal, and he thinks, as I do, that he had a narrow escape. It is also noteworthy that scant heed was given to the case; little was said about the occurrence, and none of his family, whom I have questioned, seem to have known anything of it. Very likely if my friend's attention had not been called to the matter it would never have been disclosed. The first two cases appear to have been considered as incidents hardly worth mentioning. Such indifference to a serious danger is surprising.

If among this small number of people so many cases of poisoning have come to light it would seem that the total must be very large and therefore the situation is grave enough to call for serious consideration.

How to Clean the Differential.

From H. C. White, Pennsylvania.—I am a Ford owner and take care of my car individually, and to get good results from a car you must take care of the differential and clean and get the old grease out. When you come in from a trip, jack up the rear wheels, turn a quart of kerosene in the differential, then start the engine. Let it run for two or three minutes, then take a half-inch hose, 18 inches long, place it in the differential and siphon the grease out in a pail or on the ground, then refill the differential with a quart of clean kerosene oil. Run the engine slowly for five minutes, then draw or siphon the kerosene out and fill with new grease and you have

Digitized by Google

a clean differential. This will show you how smooth the car will run on its chain bearings. Try it for the good of a Ford car and you will get results.

Installing an Ammeter.

From R. E. Ingalls, Washington.—Information is requested as to the proper method of installing a two-way, 30-0-30, ammeter on the dash of a car using the Delco Junior, single-unit, grounded-wire system. A connection from the main cable between the storage battery and generator works very satisfactory until the self-starter is used, then the ammeter promptly burns out. This is to be expected, inasmuch as the amperage is probably over 200, as I have been informed. The manufacturers of the Delco system send out a description and diagram of a method to install the ammeter. In this they advise to connect in on the wire leading from the generator to the switch; however, this only registers the discharge.

An Effective Tire Patch.

From Ray R. Lant, New York.—I have read with interest the article by C. H. Kenyon, on page 68, of your June issue, regarding a tire repair. I have a tire which had a hole similar to Mr. Kenyon's. I cleaned the opening and filled the hole with the tire plastic, making a head on both the inside and outside; then I cemented a blow-out patch inside. The tire was well worn when repaired and has had 1000 miles since, and seems to be good as long as the tire will last.

A Cementless Patch.

From Walter N. Benton, South Dakota.—I have found a handy way of putting on a patch without cement, providing you have got pure Para rubber. That is to take this rubber and wash it good with gasoline and let it get dry. Then wash it the second time and if the hole is not too big it will stay by pressing it on the tube good and tight.

Chauffeurs' Cramp.

From E. G. B., New York.—With reference to H. G. Scott's article on "chauffeurs' cramp," I wish to say that it is often caused by not giving the necessary room for the chauffeur, to allow more space in the rear of the car. Many accidents have occured owing to the cramped position of the car driver, this preventing him from being able to act quickly and easily. The writer experienced this cramp himself on one occasion and was glad when he reached his destination. The illustration, Fig. 1, clearly indicates how the cramp may be avoided by giving ample room for the chauffeur to operate the lever, pedals and steering wheel, and yet not be unnecessarily and uncomfortably cramped.

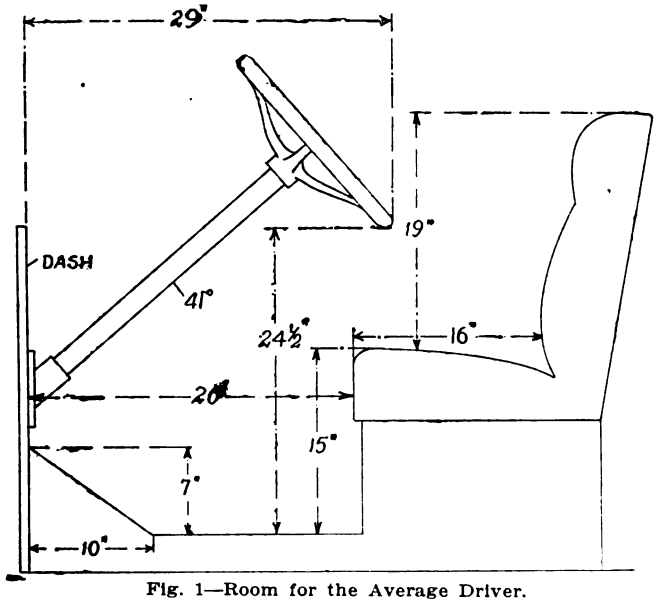


Fig. 1—Room for the Average Driver.

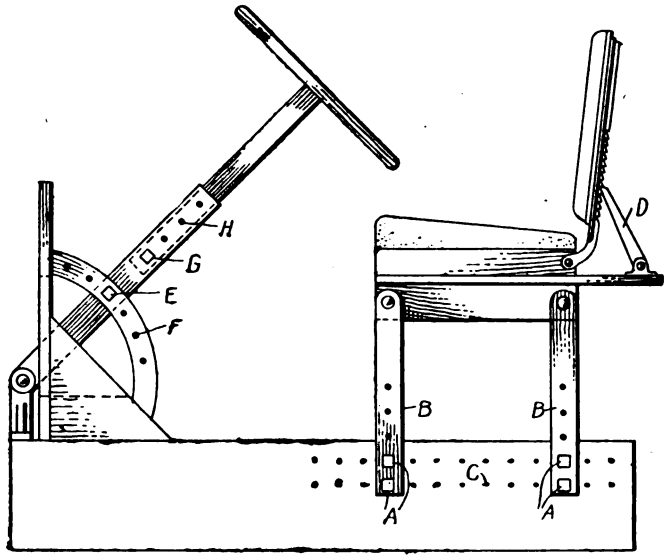

Fig. 2—Device for Regulating Seat Proportions.

In Fig. 2 is shown a useful device for those whose business it is to supply the right size and proportioned seat for the person who is to drive any car. The seat can be lowered by removing the bolts, A, and can be moved forward or backward by placing the bolt, A, through the leg, B, in the holes, C. The back of the seat can be adjusted to its proper angle by the lever, D. The steering column can be raised or lowered by removing the bolt, E, and placing it in the holes, F, or can be shortened or lengthened by taking out the bolt, G, and placing it in the holes, H. With this device put in use in the shop, garage or salesroom, chauffeurs' cramp would disappear.

Rear Axle Oil Leaks.

From H. C. White, Pennsylvania.—I am a Ford owner, a car of reliability for all purposes. I have overcome one of its evil tricks of throwing oil from one rear wheel. Many others have the same trouble. Take an old felt washer and place it or pack it next to the roller bearing and the trouble is ended. This may be of value to many that have not solved the problem.

Throttling Down Ford Cars.

From Morgan Howard, New York.—In the June number I notice one of the Ford drivers said that he could not throttle his car down to 8 or 10 miles an hour on high. I have a Ford car and use a K. W. master vibrator and five-point Bethlehem spark plugs, and I can throttle my car down to 8 or 10 miles and even lower.

A Piston Knock.

From Chas. R. Van Allen, North Dakota.—In relation to question No. 1623, headed "A Constant Knock," in the June issue, I think the answer would be a piston slap. I have some considerable trouble from this source.

WHAT MAKES GOOD BUSINESS?

It is neither confidence nor optimism. If these are based upon reason and good judgment, they are extremely advantageous to the execution of good business, but something else is required to make it. On the other hand, if confidence and hope are not based upon favorable material facts, they are sure to meet with disaster and loss. A man may have never so much confidence that he can undertake a long voyage in a leaky vessel, but it will not affect the disastrous result. On the contrary, optimism and confidence have done about as much injury as help to business. Wisdom is as often "consumed by confidence" as it is strengthened by it.

Good business is made by one thing only, namely: The desires and needs of the people and their ability to satisfy them. A manufacturer may have the hope and confidence that he can sell automobiles, but if no one has the ability to buy them, or having the ability to buy them, if no one wants them, he will be unable to dispose of them. The wants of the people and their possession of the means to gratify them, is cause; the business of supplying them is effect.

Railroads with their freight and passenger cars do not make business; the business is made by the passengers and freight ready to be transported. Overflowing merchandise warehouses do not make business; the business is made by those who have the means and the desire to purchase them. A big stock of automobiles does not make business; the business is made by those who are ready to purchase them. It is true that the creation of railroads and cars, and automobiles and other merchandise, has made business, but their existence does not make it. Nor would they have been made without the prospect of potential business created by the wants of the people and their ability to satisfy them.

The most strenuous "campaign for business," the most hopeful articles in the press, the most glowing periods of the "captains of industry," and the strictest ban upon anything expressing caution or fear, have very little effect indeed upon business improvement, provided the consuming public have not the means to purchase.

Needs and the ability to supply them are the essentials to make good business and there is no substitute for them under heaven.

TRADING STAMP GENESIS.

Some of the influential retail hardware dealers of the country have begun a campaign looking toward abolishing the trading stamp evil. May they be successful. As to that matter, the whole business of offering premiums or gifts of any sort to stimulate purchases is a plant of noxious growth that should be pulled up, root and branch, and thrown beyond the pale of business.

The idea of offering a purchaser a reward of something he does not need or want to induce him to purchase something he does need and want, is wrong in principle and baneful in practice. We are not entirely convinced that it might not well be forbidden by law on the ground of being injurious to the public welfare. Of course this trading stamp business is most hurtful to those who can least afford to suffer the loss. It mostly attracts the poor and the ignorant. It has no attractions for the well-to-do although they often tolerate it when convenient.

But the underlying cause of the trading stamp and premium craze is of far more consequence than the thing itself. Under normal conditions there would be just as much reason for a buyer of merchandise offering a premium to some one who would consent to sell it to him as for a seller to offer a premium to a buyer.

It must not be overlooked that the trading stamp evil as well as the price-cutting evil are each a result of the tremendous present day productive capacity—a productive capacity that has far outstripped the capacity of the people to consume. As a consequence we see the most strenuous efforts being made on the part of producers to find consumers, and not securing the necessary purchasers through the ordinary methods of purchase and sale, they find it expedient to offer rewards to secure sales.

The fact is, all kinds of business is being overdone rather than under-done. One of our New York City papers was complaining the other day because the farmers around the city get such a pittance for their products while the cost is high to the consumer. The blame was foisted upon the retailer. But the retailer is not getting rich, by any means. In a majority of cases he is remaining poor. The principal cause of high retail prices is the fact that there are about three times the number of retailers there should be. In a given locality where one grocer could easily handle the retail trade, there may be four or five, and the four or five necessitate an ovehead charge of at least three times that of one. Result, high prices to the consumer. But you ask the grocer why he embarked in that business

Digitized by Google

and he will say: "Well, I had to do something, and that offered as good a prospect as anything I could find." And there you are.

Of course, the foregoing is but a mere scratch of the great field of economics, but if it sets any one to thinking it will have served its purpose.

ASSEMBLED CARS.

Not long ago an assembled car was usually considered a somewhat inferior car, but among those who know, this feeling can no longer exist. A car composed of altogether assembled parts may be an unusually good one, and one which is mostly made in one factory, may be a poor one.

No manufacturer to-day produces all the parts of the car that is sold with his own firm name as an accompaniment, while as for its various accessories, such as the electrical equipment, the tires and the carburetor, 99 per cent. of the manufacturers do not make them.

In fact, wheels, radiators, bonnets, mudguards, ball and roller bearings, rear axles, chains, drip pans, valves, washers, wrenches, as well as other parts may easily be procured from specialists, and as good in quality and at less cost than they can be made by the manufacturer himself, no matter how much capital he may have. In this age of specialization and economy of production as well as superior product the most elaborate machine system and enormous output are absolutely essential.

Of course, there are some parts of an automobile that are covered by patent, and these require special construction. In such instances the manufacturer usually finds it a matter of economy to produce them himself.

But let no one ambitious to become an automobile manufacturer imagine that nothing more is necessary to produce a good car save the assembling of the parts and accessories which are produced by specialists. To produce a symmetrical car by such means is a task fraught with no end of trouble, and even when this is accomplished it is about as far away from becoming a successful automobile manufacturer as the possessor of a Webster dictionary is from becoming a successful orator or writer.

CUSTOM AND LAW.

Some one has said too severely, but not without a modicum of truth, that "Custom is the law of one description of fools and fashion of another." There is another class quite as unwise, which seems to delight in going contrary to both custom and fashion, and many in this last class are as anxious for distinction and to be conspicuous as are those who blindly follow both custom and fashion.

The fact is, however, if the custom or the fashion be a good one, there is no reason why the most wise should not make it a law, and if it be a bad or unreasonable one, why they should pay any attention whatever to it. But the thing that makes either a custom or a fashion popular is not so much its real merit—not so much as to what as to whom stands sponsor for it.

These being the facts, we believe that the concerted action of a few conspicuous and honored car owners in driving slowly and carefully and in living rigidly up to the road rules would be as contagious as any other custom or fashion practiced by the leaders of society.

Sooner or later the dangerous speed craze with its law violating and willful disregard of other users of the highways will stop. If there is no way to reach it by law, possibly it may be mitigated by the custom or fashion of courtesy. For illustration, there is no written law compelling a horse or motor-driven vehicle ahead to turn to the right and give one approaching from the rear an opportunity to pass to the left if the driver so wishes. As a result, this rule of courtesy seems to be "more honored in the breach than in the observance."

Attempts have been made in this State to enact what should be a willing custom into a written law, but they were unsuccessful largely owing to the opposition of the owners of horse-drawn vehicles. As a result, we have known of frequent instances where automobiles approaching from the rear have been maliciously prevented from passing slowly moving vehicles. Instances of this kind are so odious that if a law cannot be enacted to reach them, custom and fashion ought to be able to do so.

Indeed, in some rare instances, putting users of the highways on their honor has accomplished what the letter of the law has failed to do. The authorities of Fresno County, Cal., have recently placed at one side of each of the various highways entering the county a large signboard, with the following inscription:

MOTORISTS, ATTENTION!
YOU ARE ON YOUR HONOR.
FRESNO COUNTY HAS NO SPEED COPS.
DRIVE SO THEY WILL NOT BE NEEDED.
SPEED LIMIT, 30 MILES AN HOUR.
—Board of Supervisors.

It appears from reports that this sign has admirably served its purpose. But whether it has or has not, in cases where a law is almost impossible to enforce, "moral suasion" may well be appealed to, just as custom and fashion may properly be invoked in other instances where nothing else seems to be available.

FIRST RUDIMENTS OF PUBLICITY.

Those seeking publicity for their products, of whatever nature they may be, will do well to bear in mind that it is far better to state the merits of their own goods or devices rather than to state what is lacking in some other competing goods or devices.

There is no place where the truth of the old adage, "Comparisons are odious," is more conspicuous than in the matter of advertising. The public are anxious to know about the merits of what you have to sell, but they are rather indifferent as to your opinion of what others sell. Sometimes they are of the opinion you don't know what you are talking about, and sometimes they imagine you may be prejudiced.

It should be borne in mind that we are always glad to receive circulars or other information concerning new things in the automobile line, and as a rule we take it for granted that such information is reliable. The old method of distortion went out of date long ago. Good business men have learned that "the truth and nothing but the truth," is the best policy as well as the best principle. Yet they occasionally—and with good intent, no doubt—make comparisons, when it would be far better to merely give the merits of their own product.

And mention will be made in the editorial columns of this magazine of things that are not advertised as well as of things that are, provided they are of interest to our readers. But such notices are not

Digitized by Google

likely to be as full or complete if the thing noticed is not advertised as if it were. For in the first instance, we are not interested one way or another as to whether or not it is of benefit to the one who receives the publicity; we are interested only in its benefit to the reader. In the last instance, we want the notice to benefit the advertiser as well as the reader, and this is our duty no less than our pleasure.

"WHAT'S HE TO ME?"

It is not often a writer has an opportunity to review his own book; or having the opportunity, that he would improve it. But lest some reader may get an incorrect impression from the advertisement on another page of this issue, we beg to state that "What's He To Me?" is strictly speaking not a great story, nor—if the writer's intention were fulfilled—is there any "fine" writing in it. It is merely a plain narrative of facts, *mutatis mutandis*, and is not fiction—"all of which I knew and part of which I was." If any reader should chance to send to the publisher for a copy of the book and learn by its perusal that the writer had a purpose in writing it other than to merely amuse or interest, the author will be abundantly satisfied. The title was suggested by that old, old question, "What is my fellow man to me?"

LESSONS FOR DRIVERS.

Carelessness and Ignorance Responsible for Most Accidents.

Tossed from the Car.—A man and his wife were badly injured in Madisonburg, Pa., while traveling down a mountainous road. The brakes went wrong and the car was soon descending at a rapid speed. It finally struck a rut and threw the passengers out. They were both painfully injured and may not fully recover.

Death in the Rain.—While in a rainstorm, at Detroit, Mich., the driver of an automobile sent his machine in the path of a railroad train. It resulted in the death of three persons and the injury of three more. It appears that the driver was unable to see owing to the blinding rain.

Burned by Gasoline.—At Windsor, Colo., a man spilled some gasoline on the dashboard of his car when in the garage. When he finished filling the tank he threw the switch to start the engine and some of the gasoline that had fallen on the battery or coil ignited. With a sudden flash it enveloped him in a mass of flames. He was badly burned and it is feared he will lose his eyesight.

He Changed His Seat.—At Hartford City, Ind., while driving one man attempted to change seats with another and thus lost control of the car. The automobile jumped from the road, climbed an embankment and tore down six fence posts. Strange to say there was no great damage done.

Death Ends a Race.—At Los Angeles, Calif., there was a race between two automobiles when one struck a railroad car with terrific force. The driver of this car was killed. Other parties in the race were injured.

The Driver Looked Back.—Near Pine Lake, Wis., a young man and four women were in an automobile and the young man evidently was looking at something back of the car. At all events the automobile in which they were riding went off the road and he was killed. The young women were not seriously hurt.

A Slippery Hill.—At Logan, Utah, a car was being driven on a hill so slippery that it could not ascend it. The driver asked the four other occupants to get out and walk. They did so and he then started up the hill so rapidly that he turned out of the road and plunged down a steep embankment about 40 feet high. He was thrown out and rendered unconscious. The others rushed to his aid and in the darkness fell several feet upon the top of the car and some of them sustained severe injuries.

Plunged Through a Fence.—At Freeport, Ky., a boy was killed when a car plunged through a fence, when attempting to pass another car. One of the cars struck the fence post, beside of the road and broke eight of them, then plunged over an embankment and finally brought up in a field without any of the occupants being unseated. The occupant of the other car was not so fortunate and had his skull crushed.

Struck a Slippery Place.—In Marshfield, Wis., three persons were injured when a touring car upset on a hillside. It was going at a moderate rate only, but struck a slippery rut. The car turned over and the occupants were pinned beneath it. They were all more or less bruised, except a baby which was scarcely scratched.

A Spectacular Collision.—Two women were injured, one perhaps fatally, when two automobiles collided in Indianapolis, Ind. The impact was so great that both machines went entirely across the street, knocking pedestrians down and throwing the passengers of the car out. The drivers were careless in failing to observe the bank, but neither saw the other in time to avoid the collision.

Backed Down Hill.—Near Peoria, Ill., two men were driving a car, but were unable to make a somewhat steep hill. Near the top they met a horse and buggy coming down and the road was too narrow to permit them to pass. They jammed on the brakes but they slipped and gathering headway the car rolled down the hill. The car finally plunged into a gully and one of the occupants was killed beneath it.

Skidded in the Mud.—While driving a light car in Missoula, Mont., it skidded in the mud and before the driver could straighten it out it started down a steep embankment. It struck a telephone pole and was pretty well mutilated. Some of the occupants narrowly escaped instant death.

While Descending a Hill.—At Red Oak, Ia., a car became unmanageable in descending a hill and the occupants were thrown out. One of them subsequently died of his injuries and the others were very much cut and otherwise injured.

A Girl's Neck Broken.—Near Stroudsburg, Pa,. a night ride recently occurred which resulted in the death of one young woman and serious injuries to two others. The car was descending a steep hill and the driver was unable to take the sharp curve at its base and ran into an embankment. Some of the occupants escaped with slight injuries, but one girl's neck was broken. About the only things that were intact in the car was a quart bottle of whiskey and several bottles of beer.

Dropped Thirty Feet.—Near Fresno, Cal., a man and his wife were almost instantly killed when an

Digitized by Google

automobile which the man was driving plunged off the road and dropped 30 feet into a creek below. It appears the driver was trying to pass a buggy and ventured too near the edge of the road.

Result of A Glaring Headlight.—In Grand Rapids, Mich., glaring headlights caused a collision of two automobiles and the serious injury of two persons. A woman was driving when she became confused by the blinding lights of an approaching car. She steered her machine to the side of the road and the front axle broke, causing it to overturn. Both the woman and her husband were pinned beneath the car.

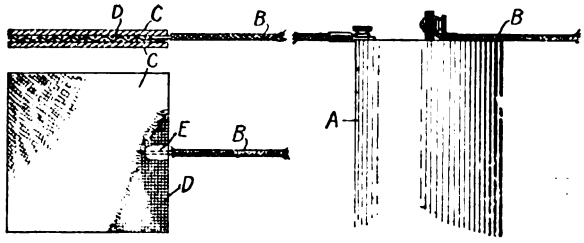
Ran Into A River.—In Chicago, Ill., an automobile containing four passengers crashed through an open draw and plunged into the river. The occupants jumped, but one of them could not free himself and sank helplessly to his death. The other three were able to swim to shore.

Crashed Into A Locomotive.—Near Mannington, W. Va., two persons were killed and two others badly injured when the car which they were driving crashed into an engine of a railway train. It appears that something went wrong with the steering gear and they were unable to control it.

In a New Machine.—In Monrovia, Calif., a man purchased a new automobile, and it is believed became confused while trying to cross a railway track. The driver and his wife were instantly killed and the other occupant severely injured by the passing locomotive. The wreckage of the machine was carried 300 yards.

Caused By A Calf.—In Alexandria, La., five young men were driving at midnight and going very fast, when suddenly a calf came across the road before the car. It was struck and carried about four yards and then fell under the wheels upsetting the car and pinning some of the occupants beneath it. One of the passengers was taken to a sanitarium and most of the others were somewhat injured.

Turned Over by the Roadside.—While driving 18 miles an hour at Huron, S. D., the blow-out of a tire threw the car suddenly to one side, with the result that the driver lost his hold on the steering wheel. The car turned over and one of the passengers was caught under it. He lived only a few hours after the accident.



Ran Out from the Sidewalk.—Recently a party of young men were riding through Chatsworth, Ill., going to a ball game when two little boys about 12 years old ran out from the sidewalk intending to get on the running board. One slipped, falling under the car and his head was crushed, killing him instantly.

Struck a Phone Pole.—At Williamsport, Ind., one man was killed, two were seriously injured and another was painfully hurt, while speeding in a high-power car which struck a culvert, swerved to the side of the road, hurtled a wire fence and clipped off a telephone post near the ground, before landing in a field bottom side up, with the occupants pinioned beneath. Immediately after the car landed the gasoline tank exploded, setting fire to the machine with the men under it.

Fatally Struck a Rut.—In Racine, Wis., a party of children and young folks took a car out for a drive with a lad of 15 at the wheel. One girl was killed and several were hurt, and we will let one of the party tell the story. She said: "Howard had permitted me to operate the car for quite a while but when it started to become dark we girls asked to be driven home quickly, and Howard taking the wheel from me began driving fast. I asked him to drive slower. Suddenly one of the front wheels of the car struck a rut in the road and it seemed as though something went wrong with the steering gear as Howard apparently lost control of the car and it went skidding into the ditch and turned turtle. We were all buried underneath the car. Persons on the road must have seen the accident because very soon they were engaged in lifting up the car. Howard was held fast in his seat by the steering wheel. Lorena Schroeder did not move when the car was lifted up and we found that she was dead. She must have been killed instantly. Eleanor Schroeder and I were but slightly injured."

For Worn Nickel Parts.

From E. G. B., New York.—The device shown in the illustration, is for the purpose of re-coating worn nickel parts on automobiles. The necessary parts to construct this device is as follows: One dry cell battery, A, two wires B, two pieces of flannel C, four to six inches square; one piece of brass gauze wire D, four to six inches square. The wire that

Re-Nickeling Apparatus.

connects with the wire gauze is soldered to it as at E. After this connection is completed, sew the flannel pads together, with the gauze between as shown. The solution to be applied to the flannel pads is 6 ounces of nitric acid and 4 ounces of mercury. The application should be made in the open air and care be taken not to inhale the fumes as they are poisonous. This mixture should stand in a 2-quart jar till it stops boiling. Then add ¾ of an ounce of nickel, and let it stand a half hour. Then fill the jar with water. Now place the loose wire of the battery upon the metal to be re-coated and with the pad rub the worn part well. This will completely re-nickel the worn place.

Long and Short Stroke Motors.

The advantages of the long-stroke motor for a given piston displacement are lower rotative speed and consequently lessened depreciation of these, as well as less vibration. The pistons are lighter on account of their smaller diameter, which begets increased mechanical efficiency; there is less distortion of pistons and cylinders due to the heat of the combustion; temperature of cylinder walls and exhaust pressure are slightly lower than with a shorter stroke. The disadvantages of a long-stroke design are the heavier construction of the cylinders and their increased height, by which the center of gravity is somewhat raised; the pistons, assuming a certain number of revolutions per minute, travel farther than those of a short-stroke motor, with consequently greater side friction; and, finally, there is

Digitized by Google

more difficulty of getting the oil past the pistons into the cylinder space.

Deadly Exhaust Gases.

From E. L. Ireland, Nebraska.—In a late number of your magazine, I notice an article on auto gas poisoning by Dr. Lester Curtis, of Illinois. His warning is indeed important. One should avoid working about a car when exposed to the exhaust gas while the engine is running. There should be special caution used not to run the engine in the garage while the doors are closed.

This danger of exhaust gas has been forcibly brought to my attention in two instances. In one case a brother of mine who was a very successful practicing physician was found dead at the rear end of his car with the engine running. The rear axle was resting on the jack which he had not removed before starting the engine. Evidently upon attempting to remove the jack from under the rear axle while the engine was running he was suddenly overcome by the exhaust gas thus leaving no possible chance to save himself.

I will cite another case that I know about personally. The Union Pacific Railroad has large gas engine driven passenger cars on some lines of its railway system. A few years ago such a car operated out from Omaha. On a certain occasion two of these motor cars were hitched together and when they reached the next station it was discovered that the motorman of the second car was overcome by the exhaust of the car ahead. The front end of his car was of course right behind the exhaust of the car ahead. This motorman died without regaining consciousness. It seems that one cannot discover his own danger in time to save himself. The particular danger is in working about the exhaust or under the car or in remaining in the garage with the doors and windows closed while the engine is running.

A Cheap Garage.

From E. G. B., New York.—The garage shown in the illustrations is made of brick and covers an area of 27 feet 1 inch by 16 feet 1 inch. It can be erected at a comparatively low cost. The plan, elevations and sectional views presented have been worked out carefully by the writer. There is no reason why even a cheap garage may not have a convenient plan and an artistic exterior, and I have enjoyed working out the problem. The arrangement which I have adopted makes a compact and convenient garage with little waste room. This last named feature may be incorporated in any garage, but it is one that is often neglected. The foundation excavation or ditch is 3 feet 7 inches deep. As for materials, brick being unusually cheap and of easy handling, I have used it for the foundation and walls, and it may also be used for the flooring and pit if so desired. The brick should be hard burned brick, laid in rich gray lime mortar, with all joints well slushed. I have adopted the flat style of roof, covered with sheet tin, as this is both cheap and otherwise satisfactory. It should be a good brand of I. C. tin, 14 by 20 inches, with flat seams, and made secure at the edges in contact with the brick wall. The windows on the sides and rear are all the same size. The two front windows each side of the door are smaller, being 5 feet by 2 feet. The window frames are all for light windows, and are box frames. The door of the garage is as per details, 1¾ inches thick with moulded panels. The upper panels are of glass to give additional light. The ceiling and roof boards are ⅞ by 4 inches Texas star flooring boards. The list of material used in the construction of this garage is as follows:

Lumber for roof beams, 365½ feet —15 feet 6½ inches x 3 x 6 inch beams.

Lumber for roof boards, 112 boards, 4 inches x 13 feet, or 1,456 feet.

Lumber for ceiling, the same as for the roof.

Tin required for the roof, 476 square feet.

Stone projection on the roof, 5 stones, 5 feet 2⅜ inches x 9¾ x 4½. Four stones, 4 feet 1¾ inches x 9¾ inches by 4½ inches.

Bricks used in the construction, 26,376.

Cement for floor and pit, 429 square feet.

HOW MANY CYLINDERS?

And Other Problems of Pleasure Car Motor Design.

A. P. Bush, Consulting Engineer, before the Society of Automobile Engineers in New York.—There is certainly a majority and probably a unanimous opinion among engineers that the small-bore long-stroke high-speed motor is the best adapted to automobile service, at least in pleasure vehicles. Let us make a brief analysis and see if we cannot accept this statement as an axiom, and base our further considerations of motor car engine design and construction upon this one fundamental truth.

In stationary work efficiency has pretty generally increased with the size of the cylinder, but this apparent contradiction can be easily rationalized if we begin at the beginning and consider the conditions and requirements of the class of motor car service in question. In the first place, weight reduction is a prime requirement; and relatively high speed is the most obvious method of securing weight reduction. In the second place, the class of service under consideration demands flexibility throughout a range unapproached in any other service. If from three to sixty m. p. h. be accepted as reasonable minimum and maximum road speeds on top gear, we have a 95 per cent. speed fluctuation, throughout which speed range our motors must operate satisfactorily at from zero to full power. In a high-speed automobile engine this might represent a speed range of from 125 r. p. m. to 2,500 r. p. m ., a range not only not impossible but not even difficult. For an extreme comparison, let us assume an attempt to get the same speed range on a large engine capable of say a maximum of 100 r. p. m., and we have the impossible minimum of 5 r. p. m. required.

It therefore becomes apparent that we can accept this small high-speed engine as the best adapted to automobile service because of two fundamental requirements, namely: low weight and flexibility. Before we can proceed intelligently in consideration of types and details, we should determine within some limits two things: how small a cylinder should be and how high the maximum speed should be; and in connection with these two questions we must give consideration to efficiency. Power is secured from an internal combustion engine, as we all know, in the following manner: relatively cool gases consisting principally of inert nitrogen are compressed by a piston. At the point of highest compression the relatively small amount of atmospheric oxygen and a suitable proportion of hydro-carbon gas by combustion suddenly raise the temperature and consequently the pressure of the whole volume of compressed gases. As the piston moves outward on the stroke succeeding the compression stroke, these high-temperature high-pressure gases do work upon it by means of their expansion. By keeping in mind this elementary outline we can by a little analytical reasoning begin to see some other reasons why our automobile engine must be both small and high-speed, and also why it cannot be too small without being too high-speed. Since its production of power is necessarily accompanied by high temperatures, and also developed by successive cycles in the same cylinder, and since the conduction of heat is limited in the materials we must use, it becomes apparent at once that there is a limit to the number of cycles per minute to which the non-water-jacketed parts (piston and exhaust valve) which come in direct contact with the combustion, can be subjected successfully. That this limit exists is evident from the necessity of water-jacketing these parts (pistons and exhaust valves) on large stationary engines, in spite of relatively low number of cycles per minute. It is well known that medium-sized engines, of say 10 inch piston diameter, which operate successfully at low speeds without water-jacketed exhaust valves and pistons, are incapable of being operated successfully at high speed under full load.

From this much of our analysis we might conclude that the smaller the cylinder diameter the better, but there is also one fundamental reason why the piston diameter should be kept as great as is consistent with continuous operation at full load and maximum speed, namely: the superficial area of similar volumes varies as the square of their similar line dimensions, while the volume varies as the cube of their similar line dimensions. This means that the smaller the combustion chamber, the greater is its superficial area in proportion to its volume, and consequently at a given rate of speed, the greater will be the amount of heat lost through the relatively cold confining walls.

The heat loss through the limiting walls of the combustion chamber is, of course, a function of the wall area factor and the time factor divided by the volume.

Since the time factor is in direct proportion to the speed, it is obvious that the smaller the volume of the combustion chamber, the greater the speed should and can be.

There is another effect of wall area to be considered. It is well known that the efficiency of a given volume of mixture handled as outlined increases as the compression is increased up to certain or, perhaps I should say, uncertain limits. The cooler the charge is at the time of ignition, the higher the compression can be carried.

The non-water-jacketed parts of the combustion chamber, while lower in temperature than the expanding charge, are considerably higher in temperature than the incoming charge. This being true, these parts pre-heat the charge during compression and thereby tend to reduce the efficiency of the motor. This pre-heating again is affected by the time factor and puts another premium on high speed.

In our analysis so far we have already noted that a physical characteristic of our structural materials (their heat conductivity) tends to set a limit on cylinder size for any given maximum speed at full power. There is a natural law which must also be considered in determining not only size but proportions as well. The strength of any structural element of any given material increases in proportion to its size as its size decreases. To illustrate, a steel ball one inch in diameter will carry several thousand times its own weight, while a ball of the same material one mile in diameter would fall apart of its own weight.

Two fundamental necessities in motor car service (light weight and great flexibility) can be met satisfactorily only by a motor design capable of continuous operation under full load at speeds at least as high as 2,500 r. p. m. From the preceding analysis it is obvious that the piston and exhaust valve diameters will be definitely limited, if satisfactory performance and durability are to be secured in the

Digitized by Google

hands of the average user, and it is equally demonstrated that we must not go too far below these limits if satisfactory efficiency is to be secured, because of the already noted geometrical fact of relative volume and area ratios, in connection with the pre-heating and cooling effect of combustion chamber walls.

I will not attempt to say just what the best compromise between these two conflicting limitations is, but in my opinion the zone of satisfactory cylinder diameters lies between a maximum of 3½ inches and a minmum of 2½ inches, and I shall base further consideration upon this assumption.

Bore-Stroke Ratio.

Before we proceed to a discussion of advisable ratios between bore and stroke, I would like to consider briefly, from the efficiency standpoint only, the question of combustion chamber form. Heat and therefore power losses from the combustion chamber are a function of wall area and time. Actual areas as against superficial dimensional areas are least when the surfaces are smoothest; therefore it is desirable, if possible, to have the entire combustion chamber wall surfaces machined. Since a sphere has the least superficial area in proportion to its volume, it is also desirable that the combustion chamber form approach that of the sphere as nearly as structural limitations will permit. If it is found possible to solve satisfactorily the mechanical problems involved, we can safely conclude that inverted valves heated directly in the cylinder head give nearly if not quite the best form of combustion chamber which it is commercially possible to secure. The walls are entirely machined. The combustion chamber volume is naturally very exact, the form being cylindrical. In my opinion this is the most desirable form of combustion chamber and arrangement of poppet valves, and the mechanical problems involved have been solved satisfactorily.

Limiting further discussion to this type and arrangement, let us proceed to an analysis of the next most difficult compromise: the most advisable length of stroke; considering it first with reference to cylinder diameter, and second with reference to mechanical and structural limitations. From the standpoint of increased efficiency by reduction of heat losses through the combustion chamber wall, we must admit at once that for any given cylinder diameter the longer the stroke the better. Our consideration of this problem in compromise resolves itself into the question of how long a stroke can be secured without sacrificing more than is gained. With the assumed form of cylinder and combustion chamber the valves are limited to an outside diameter slightly less than one-half the bore of cylinder and to a throat diameter further reduced by the width of the valve seat. To meet the demands of flexibility, a power curve must be secured that will give good values above 2,500 r. p. m. We have therefore what we may term the valve-chamber-limit on stroke. This limit is sometimes urged as an objection to the specified type of motor. Very satisfactory power curve characteristics can be sevured with a stroke-bore ratio as high as 1.5 to 1, and the said type of cylinder construction and valve arrangement will show with as low a ratio as 1.33 to 1 superior efficiency to that of the longest stroke L-type cylinder construction which it is practicable or advisable to use.

Connecting-Rod Length.

So far our reasoning has led us to conclude that the modern tendency in engine design is in harmony with natural laws. One detail which there is a tendency to develop is, I think, in opposition to a natural law governing efficiency. I refer to the ratio of connecting-rod length to stroke. While there are the mechanical considerations of vibration and stress which put a premium upon connecting-rod length, the time factor as affecting combustion chamber efficiency puts a definite penalty on connecting-rod length. It is commercially impossible to make a rapidly working piston absolutely gas-tight. The temperature and pressure in the combustion chamber are necessarily higher at the beginning than at the end of the working stroke and the ratio of wall area to volume is greater at the beginning than at the end of the working stroke. Therefore, because of these three considerations, mechanical leakage, temperature difference and wall-area-to-volume difference, the time factor is most detrimental during the later portion of the compression and the earlier portion of the working stroke. Due to its angularity, the shorter the connecting-rod the less the time proportion of the compression and working strokes, coincident with high pressures, high temperatures and high wall-to-volume ratios; therefore, the shorter the connecting-rod the higher the combustion chamber efficiency at any given number of revolutions per minute.

Of course, high side pressure between the cylinder wall and piston is urged against short connecting-rods with their high angularity. However, with lubrication varied (as it properly should be) in proportion to the pressure delivered by the expanding charge upon the piston head, this becomes a negligible factor.

The questions of vibration and stress are, I believe, the two factors which limit the advisable shortening of the connecting-rod. These would disappear entirely if it were possible to construct pistons and connecting-rod upper-ends of zero weight. I have called your attention to this phase of motor design to emphasize the extreme value of light-weight pistons. It is not improbable that some of the light-weight alloys will be found satisfactory in small diameter pistons, but fail in large diameter pistons.

Let us assume, for the purpose of further discussion, that a cylinder of 3 inch bore and 4½ inch stroke, with inverted or overhead valves, will give the highest average efficiency and still meet satisfactorily the requirement of continuous prformance under full load at speeds at least as high as 2,500 r. p. m., or in other words when subjected to maximum temperature and pressures at least as often as 1,250 times per minute.

Number of Cylinders.

These cylinder dimensions give a displacement of approximately 32 cubic inches and can safely be relied upon to give, in the hands of the ordinary user, at least 3.2 h. p. at 1,000 r. p. m. (500 cycles per minute), and to approximate proportional power delivery throughout a wide range of higher and lower speed.

If two of these cylinders be combined in a two-cylinder engine, we have double the piston displacement per revolution with less than double the total engine friction per cylinder, and again, if the num-

Digitized by Google

ber of cylinders be doubled, we again double the piston displacement but do not quite double the total engine friction per cylinder. In fact, increasing the power by multiplying the cylinders has a tendency to increase the efficiency of an engine so long as the same power per impulse is required.

The only problem which tends to decrease efficiency, as the number of cylinders is increased, is the problem of uniform and adequate charging of the cylinders.

I assume that no one will question the axiomatic truth that all other things being equal, the greater the number of impulses per revolution of the crankshaft, the greater will be the flexibility of the motor. This increase in flexibility due to increased cylinder numbers is of maximum value in automobile service, because it is an increase which is added entirely at the lower end of the speed range.

In view of these two obvious truths it becomes at once apparent that the problem of increasing the power and flexibility of an automobile on top gear is solved with the least reduction in efficiency by increasing the number instead of the size of the cylinders. There are other advantages besides efficiency in meeting the demand for greater top gear capacity by increased number rather than increased size of cylinders. One of them is the law already stated that a structural element is proportionately stronger as its size decreases, with its obvious corollary that the smaller moving parts are capable of operating more continuously at high speeds. Another is that the greater number of impulses tend to produce an engine whose operation is more satisfactory at lower speed. To sum up, the frequent-impulse engine is more pleasing in its operation throughout its entire speed range. Its speed range is wider, its durability should be greater, and its efficiency should be higher for a given degree of road ability.

Having started to reason along this line, one might be tempted to jump to the conclusion that there is no limit to the number of cylinders which are advisable. A moment's consideration will show the fallacy of such a conclusion. The end to be secured is to make the car as a whole more desirable from the user's standpoint. As in the achievement of any other worth-while purpose, there is a price which must be paid. The price which must be paid in the achievement of this particular end is an increase in mechanical complication. If we are agreed that the end is desirable and that the means outlined will achieve it, the problem which remains for discussion is the very common-sense one of how low we can make the price.

Fours.

There is obviously no reason for discussing any number of cylinders less than four, as it has been conclusively demonstrated that that number gives the least number of impulses per revolution of crankshaft that will be tolerated by the most economical class of motor car buyers. I believe that the four-cylinder motor will continue to be standard for the lowest price class of automobiles so long as the four-cycle internal combustion engine continues to be the acceptd source of power for this type of vehicle.

As I have already pointed out, two exceedingly important factors in the comfort value of a car, namely, power and flexibility, can be bettered by increasing the number instead of the size of the cylinders, with less sacrifice of fuel efficiency and with an actual gain in durability.

Sixes.

Let us now compare the two first steps beyond the four-cylinder vertical motor in relation to increased comfort value. I refer to the six-cylinder vertical and the eight-cylinder V-type motors.

For purposes of comparison let us assume the same cylinder dimensions, 3 inch bore and 4½ inch stroke. The six-cylinder motor will give an increase of 50 per cent. in power; the number of impulses per revolution will be increased 50 per cent. The cost of this increase will be the two extra cylinders with their pistons, connecting-rods, valves, valve operating mechanism and other minor supplemental parts. Also we must depart from the simple all-in-plane crankshaft of the four-cylinder motor, and to keep the same passenger capacity we must increase the wheelbase of the car something over two cylinder-diameters.

Eights.

The advantages of the eight consist in a 100 per cent. increase in power and a 100 per cent. increase in number of impulses per revolution. The increase in the number of major working parts is, as in the six, substantially in proportion to the number of cylinders added. I say substantially, because we must except two of the major working parts, the crankshaft and camshaft with their interconnecting gear, the number of these parts being the same independently of the number of cylinders.

In the eight V, however, we have this much less price to pay for the greater increase in power and flexibility; the crankshaft remains of the four-cylinder all-in-plane type; the increase in wheelbase need not be more than half of one cylinder-diameter.

I think, therefore, that we must conclude that the eight-cylinder V-type motor makes possible a decidedly greater increase in the comfort value of the car, as effected by motor performance, than the six-cylinder vertical, at a cost in dollars and cents and in car weight at least as low.

Twelves.

As a corollary to this, I think we must conclude that any lengthening of the wheelbase of the car, for increased engine space, and the introduction of a three-place crankshaft, can be justified only in case we wish to secure a 200 per cent. increase in number of impulses per revolution and a 200 per cent. increase in piston displacement over a four of equal cylinder dimensions; or in other words, if we wish to increase the comfort value of the car as effected by engine performance up to the point where the twelve-cylinder V-type motor is advisable.

V Fours.

I have been asked why, if a V eight or a V twelve is a logical motor type, why not a V four? In answer I would call attention to the fact that in V motors, if the impulses are to be evenly spaced and if advantage is to be taken of the possibility of working two pistons on each crank-throw, the angle between the V is the angle of crankshaft rotation between impulses, and the V four, having half the number of cylinders and consequently half the number of impulses per revolution, would require an angle within the V twice that of the eight, that is, twice 90 degrees, or 180 degrees. This would ob-

Digitized by Google

viously give a form of engine quite impossible of installation within tolerable hood dimensions.

Vibration.

In connection with V motors in general, some interesting facts in major vibratory tendencies appear. Taking the V four, for example, if all cylinders would work properly on a single crank-throw, as compared with the vertical four of the same cylinder dimensions, all major vertical vibratory tendencies would disappear and in their place would be found a horizontal vibratory tendency just twice as great as the vertical vibratory tendency of the vertical four.

In the V eight as compared with the vertical four of the same cylinder dimensions, the vertical vibratory tendency disappears and in its stead there is a horizontal vibratory tendency of the same general characteristic, 1 3/7 times as great as the vertical vibratory tendency of the vertical four.

In this connection it has been interesting to observe that a properly constructed chassis seems much better able to absorb this horizontal vibratory tendency than the vertical vibratory tendency of the vertical four.

The V twelve seems to have the same major vibratory tendencies and characteristics as the vertical six; that is, instead of a tendency to reciprocate the entire motor mass with four reversals per revolution of the crankshaft, as in the vertical four and V eight, there is a tendency to set up periodic vibrations within the motor mass, the amplitude of these vibrations being in proportion to the work the engine is doing.

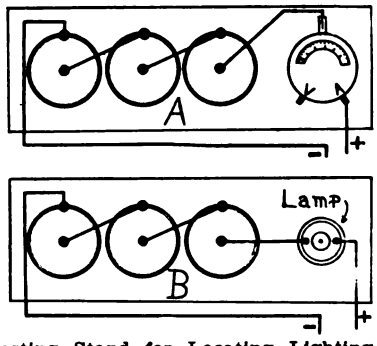
This six vertical and twelve V vibrations seems to be a function of overcoming it, by increased crankshaft and crankcase rigidity, is, some years ago by some of the foreign engine builders by use of a friction damping method. What we might term the American method of overcoming it, by increased crankshaft and crankcase rigidity, is, I think, much more scientific and workmanlike.

Overhead-Valve Construction.

I have referred previously to the fundamental advantages of the inverted or overhead-valve type of construction and made the statement that the problems of valve operation have been solved satisfactorily. In proof of the thermal advantages of this type, I would like to call your attention to the fact that in automobile engines this is the only cylinder type which has survived in the direct or air-cooled engine; and I believe this survival has been due almost entirely to, first, the inherent thermal superiority of this cylinder form, and, second, the brilliantly simple manner in which the problem of valve operation has been met, a method so simple that it has apparently escaped the attention and understanding of engine designers in general.

The overhead rocker type of valve-operating mechanism has been criticized as being noisy, because of the greater mass of the moving parts involved. With valve rockers pivoted at their centers, this is an obvious and inherent defect. It is the Franklin company's practice to locate the rocker pivot twice as far from the center line of the valve stem as from the center line of the push-rod. This means that for the same valving characteristics, the cam-rider, the push-rod and the push-rod end of the rocker have just half the movement, and consequently half the maximum velocity of the valve, and in turn just one-fourth the kinetic value in proportion to their weight, with the result that the kinetic value of all of the moving masses of the valve-operating mechanism is nearly if not quite as low as in the average practice in L or T type of engine designs.

The selection of this best commercially possible thermal form of cylinder and valve arrangement, in connection with the really splendid bit of engineering skill, has secured commercial quietness of valve operation in the air-cooled type of engine mentioned, in which owing to the lack of water-jackets quietness is most difficult to achieve.



I believe that by taking one more step we can make this indirect valve-operating mechanism commercially superior to any other known type. By making the position of the offset rocker-pivot adjustable, the adjustment parts thus becoming stationary, in connection with the offset rocker and lightened moving parts there will be secured kinetic values at least as low as those of the best direct-action types, in proportion to the effective valving. In addition we attain a convenience of adjustment for the user that has not been approximately heretofore in any constructions with which I am familiar.

Conclusion.

Like the mechanism which we have been considering, a paper of this kind must be a compromise. From the standpoint of your patience, it is without doubt already too long, and from the standpoint of anything like a thorough discussion of the problems under consideration it is much too short. I have only attempted to touch upon the most important and fundamental problems of engine design and their relation to so-called pleasure car service.

Electric Testing Stand.

Grounds or short circuits in the lighting and starting system, and locating a wire of a group run through a conduit, requires a knowledge of the system and the use of certain equipment. Any owner can make a testing outfit which will serve all practical purposes, and which will form a valuable addition to the garage equipment.

Home-Made Testing Stand for Locating Lighting, Starting and Ignition Troubles.

Take a board about 12 inches long and secure three dry cells wired in series; that is, connect a zinc terminal of one to the carbon of the next and so on, leaving one carbon and one zinc post free. Take two 10-foot sections of lamp cord and attach one to the zinc post as shown at A. Attach a volt-ammeter to the board as shown and wire it to the carbon post of the right-hand cell. The other section of lamp cord is attached to the ammeter side of the instrument when testing for amperage, or to the

Digitized by Google

volt post when determining voltage. The sketch at B shows a similar arrangement with a 3-volt lamp.

To employ the tester for locating a broken wire in a circuit, touch a loop of the lamp cord to each end of the suspected wire. If the lamp lights, the circuit is unbroken. If the circuit or wire be broken the lamp will not burn. To locate short circuits or grounds, displace one end of the wire and attach it to one loop. Touch the other end of the other loop or lamp cord to the metal of the chassis or parts near which the wire runs. The lamp will not light if the wire be in good condition. If it does, it indicates a ground.

The tester makes it a simple matter to locate a wire of a number in a conduit. Attach one end of any wire to a loop and use the other loop by touching it to the other ends of the group until the lamp lights, which will indicate the correct wire as the circuit is closed. It should be mentioned that the insulation should be removed from the free ends of the lamp cord. The testing stand can be utilized in many ways, but the ammeter side should not be employed when testing storage batteries.

CONDUCTED BY M. KEITH DUNHAM, OXY-ACETYLENE ENGINEER.

Readers are requested to state their questions clearly and fully, but as concisely as possible. It is hoped the information given will be of general interest as well as of value to each inquirer.

Welding Small Pieces.

From Walter R. Murff, Mississippi.—I have an Economy Junior welding plant, made by the Economy Welding Machine Co., of Kansas City, Mo. To successfully weld cast iron or steel 3/8 inch thick, and the piece weighing 5 pounds, I have to bring the metal to a red heat with the other heat, and hold at this heat until the weld is finished. I want to know if this method is right. Is the Economy Junior machine too small to make a successful welding outfit?

Answer.—Using charcoal or other methods of superheating a weld can only result in a better weld than if no other heat is used except the welding flame. At times, of course, it may be wholly impossible to heat with other methods and if the limit of your torch is three-eighths steel, you are certainly working under a big handicap.

For a small repair shop, the welding torch should be capable of handling one inch steel, without superheating. Your trouble then is undoubtedly the size of your welding apparatus. If you were using tank or dissolved acetylene, it would merely mean the purchase by you of larger tips for your welding torch, as both the regulators would be capable of delivering the necessary volume of gas.

I believe the plant you are using generates both gases: An acetylene generator of the carbide to water type, to operate safely and deliver reasonably pure gas, must not be called upon to deliver more than one foot of gas hourly for each pound of carbide capacity,—that is a generator with a capacity of 20 pounds of carbide should not generate more than 20 feet per hour. To weld three-eighths inch steel cold requires an acetylene consumption double this number of feet, so that you can readily see that if your generator is a small one, you are necessarily limited as to the size of your flame.

Would suggest you write the manufacturers and find out on what basis you could trade in your present equipment for one capable of handling your work.

Cutting Steel Bars.

From J. L. Schrieber, Mississippi.—I have some steel about 1/6 to 1/8 inch thick. I cannot cut it with a cold chisel. It is too hard. Can I cut it with an oxy-acetylene torch? Or will it draw the temper out? I want to cut it into strips about 3/4 inch wide. Will you please tell me what kind of an outfit I should get.

Answer.—Your proposition presents some difficulties but if the right outfit is purchased and you handle it intelligently, it will do this work satisfactorily.

Cutting with oxygen requires a flame, as well as a stream of oxygen. The flame merely heats the metal hot enough to permit the oxygen to attack the metal—to oxidize it—and thereafter the iron or steel is the fuel which is burnt up by the oxygen. The heat of this combustion in your instance must be confined to a very narrow limit; therefore the flame must be very small, the oxygen stream very small and so directed that it will not spread. Because of the speed of the process, the temper of the metal should not be drawn more than 1/32 of an inch and the width of the scarf or cut be not more than this distance also. Acetylene is not necessary in this instance—in fact, a gas of less heating power, such as hydrogen or coal gas, is more desirable.

In practice, you may find it necessary to clamp two or more of these plates together when cutting, in order to prevent to some extent combustion into the sides of the plates rather than through them or to clamp a copper plate to the steel plate you are cutting, so that the copper plate will absorb some of the heat. Write to any or all of the advertisers, outlining your requirements and make your purchase on a guarantee basis, with these facts in mind.

Welding a Crankshaft.

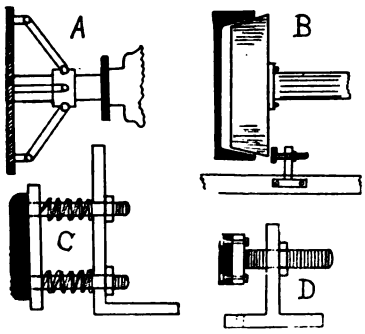
From Garden City Garage, Florida.—We wish to ask your expert advice as to how to go at welding a four-cylinder automobile crankshaft, so that it can be guaranteed to hold and run true. An early reply will please us very much.

Answer.—First prepare the break by grinding from both sides on an angle of about 45 degrees to a chisel edge—not to a point, as the latter way will allow the molten metal from the welding rod to attach itself to cold metal and it will be extremely difficult to effect a good weld. If the break is flush with one of the webs (a common break), simply grind the round portion of the shaft, leaving the web as it is.

If you have no V blocks, put the broken shaft in the lathe and start welding; if the break is in such a position that it is possible to do so, you can do the entire job in the lathe. If, however, it is necessary to get the shaft on end for some portion of the weld, take it out of the lathe when the welding has progressed far enough to hold the pieces firmly together and complete the weld on the welding table,

Digitized by Google

or better still in a forge or charcoal fire, where you can keep the metal adjacent to the weld at a red heat by the fire, while making the weld with the torch. After the weld is completed, reheat in the fire slowly to a light red heat and when the shaft is cool, put it into the lathe to straighten or true it up.



No matter how careful you have been in getting the shaft in alignment before welding, it is always necessary to straighten after welding, since the heat has to a certain extent, distorted the shaft in the vicinity of the weld. This straightening is rarely a long job, however, and you should look upon the shaft merely as one which is slightly bent or twisted and treat it accordingly.

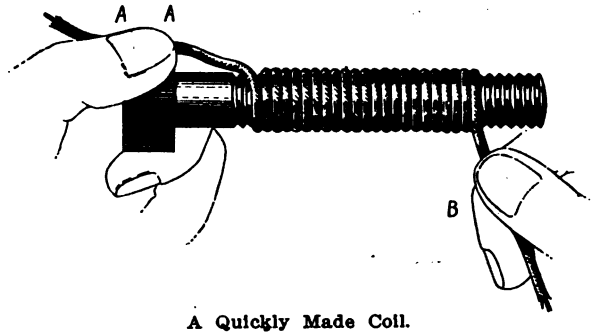
The most important part comes here—the skill and judgment of the operator. If the shaft is one of a high carbon content, even a skilful operator will have his hands full in making a successful weld and an unskilful one would not get 50 per cent. strength. If it is comparatively low in carbon, the job is not so difficult. The welding rod should be as near as practical the same material as the shaft, the adjustment of the flame (as described in the July issue) most carefully made and the entire welding carefully carried out.

Steel welding, while apparently the most simple with the oxy-acetylene torch, is really the most difficult and unless you have welded this metal to a considerable extent, by all means do not start on a crankshaft, where in the event of your being unsuccessful in making a strong weld, the damage would be very high. Instead, practice first on mild steel plates, starting in on about ⅛ inch and gradually increasing till you are welding ½ in. Test each plate by bending back and forth in a vise until you know how to weld—and then tackle the crankshaft.

Clutch Stops or Brakes.

The failure to shift gears is not always due to the lack of skill of the operator, as it is not possible to change from one speed to another with some types of cars without a clashing noise. This is due to the clutch shaft spinning, imparting energy to the constant mesh gears. Many times the male portion of the clutch will continue to spin after it is fully disengaged, a condition due to the periphery of the clutch contacting with the flywheel member or female section. A worn bearing is usually the cause. This may be determined by starting the motor, engaging and disengaging the clutch, and noting if it continues to spin.

Clutch Stops.



Clutch stops or brakes are fitted to a number of modern cars and are, as a rule, made adjustable. It is a simple matter to design and fit one of these devices to the old car, and the sketches shown will suggest four methods. That at B is adaptable to a cone type of clutch and consists of a T piece of metal bolted to the cross frame member or other convenient place. The stop is constructed of a bolt screwed through the T support and locked by a nut. The stop proper is made by securing a piece of sole leather to the bolt.

The design illustrated at A can be used with the dry disc or plate type of clutch. Secured to the gearset housing by the screws retaining the felt washer used to prevent leakage of the lubricant, is a disc of leather which can be cut so that it can be slipped over the clutch shaft. When the clutch is fully disengaged, the collar contacts with the pad, slowing down the clutch.

The illustration at C shows a stop of the adjustable type with springs for cushioning the contact. The stop is equipped with a leather pad which, like the design at D, is countersunk so that the bolts will be well below the surface. The drawing at D gives in detail the stop shown installed at B. The construction and installation will vary according to the design of car, but a little study will enable one to make and fit a satisfactory clutch brake at a slight expense.

Making a Coil.

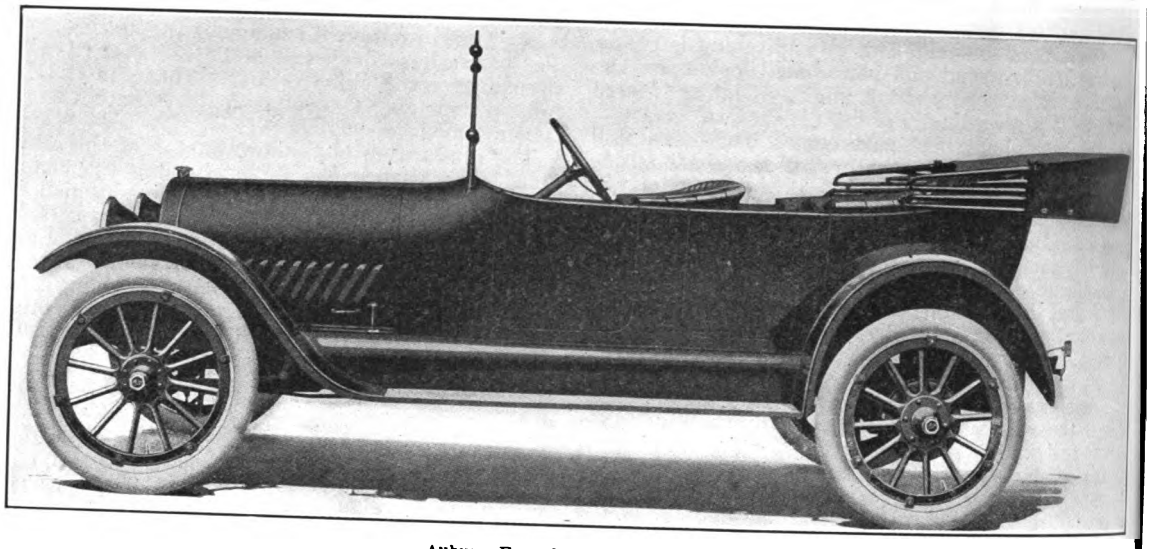
From E. G. B., New York.—The illustration shown is a simple method employed in making a coil, either for the battery wires, or for coil connections. Holding the wire as at A with the thumb, and pressing on the bolt head firmly, holds the wire in place while winding it with the other hand, as shown at B. A bolt or round rod can be used to good advantage in forming a coil of this kind.

A Quickly Made Coil.

A Stone Bruise.

When the tire has hit a stone with considerable force, especially if the tire is not fully inflated, the inner surface of the tire will show injury to the fabric when the rubber on the tread has no mark of the injury. Such an injury should be repaired by putting a fabric patch over the injured place, and then inserting an inner protector all around the casing.

Vibrator Screws.



If the screws that hold the small brass brackets to the vibrator box become worn so that they do not hold, do not use longer screws. Longer screws may injure the windings of the coil and spoil the vibrator. Better put a metal band clear around the box and attach to dash with small bolts.

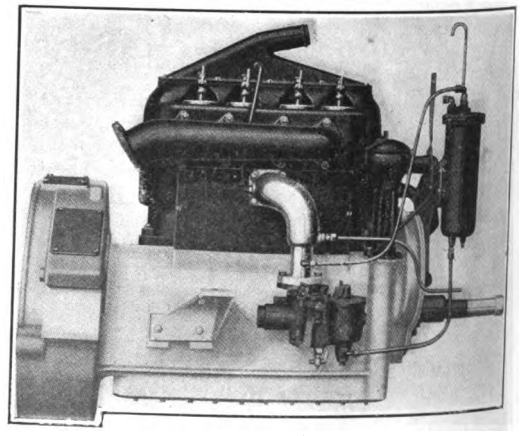
MUCH FOR THE MONEY.

An Unusual Value for the New Auburn Touring Car.

The Auburn automobile, made by the Auburn Automobile Company, Auburn, Ind., is one of the surprises of even this year of new models and lower prices. Of course, no illustrations do it justice, for an inferior car will make as clean and attractive picture as the best that money and talent can supply. The beauty of an Auburn lies as much in the consistency of its performance as in the lines and finish that delight the eye of an artist. The body is a masterpiece of the motor car builders' art and there is an impressive artistry and refinement in every line.

Auburn Four-Cylinder 38 Horsepower.



In the four-cylinder 38 horsepower touring car model, illustrated herewith, the chassis has a three-point unit power plant that includes motor, clutch and transmission. The motor is T-head, cast en bloc, water-cooled. The cylinders have a bore of 3⅞ and a stroke of 5 inches, a stroke bore ratio of 1.29 with an S. A. E. formula horsepower rating of 24 and on brake test 38.

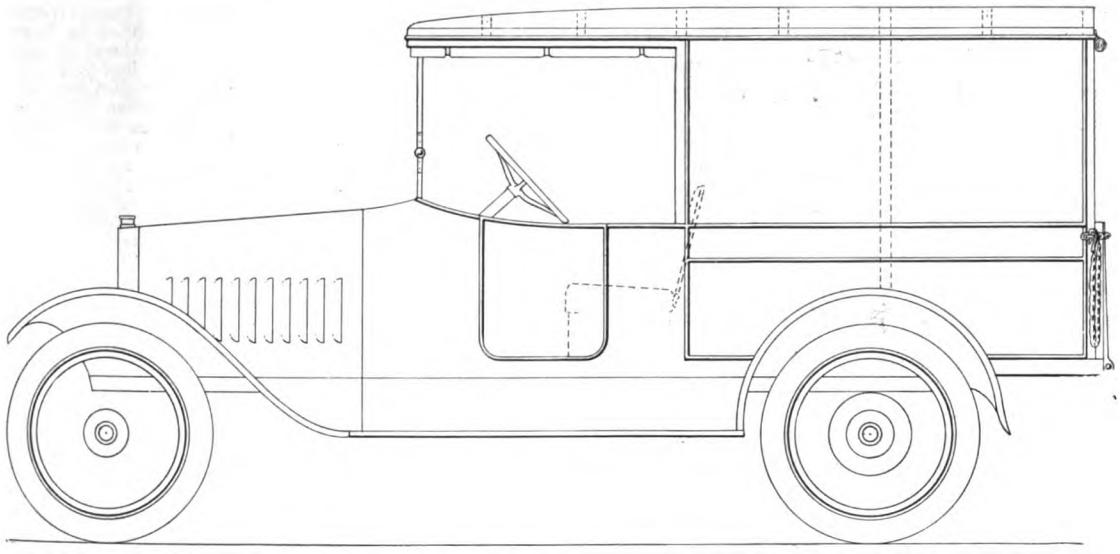
The valves are unusually large, giving an open port of 2 inches. All valves are interchangeable and provided with cast iron heads electrically welded on nickel steel stems and operated by adjustable tappets which are case hardened and accurately ground to size.

To insure perfect carburetion the intake manifold passes through the cylinder block which completely jackets it with hot water. The carburetor is located on right side of motor and is automatic. The motor is provided with a centrifugal water pump located in front of the gear case.

The motor, while unusually short for its displacement, is provided with a three-bearing crank shaft, the cam shaft with three large bearings. The cylinders, pistons and piston rings are cast from a special grade of iron and are accurately ground to size. Each piston is fitted with three eccentric rings. They are ground on both sides, assuring a perfect fit in the piston as well as at the wall of the cylinder. The piston pins are made of chrome nickel steel hardened and ground. The connecting rods and crank shaft are of dropped forged carbon steel. The lubrication of this motor is by the patented splash system. The timing gears are spiral cut. Both the pump shaft and crank shaft gears are drop forged. The electric current for lighting, starting and ignition is created by generator and stored in storage battery. The starting motor is installed back of flywheel housing so that its pinion meshes with a hardened ring gear on rim of flywheel.

The frame is of the best steel channel section; all thoroughly braced and hot riveted. The springs are floating on rear axle pivoted to frame at center and linked in front, allowing free play in the spring action. The front axle is drop forged "I" beam section, heat treated, with integral yokes, drop forged steering spindles. The drive is by shaft through universal joint to floating rear axle. The steering gear is worm and gear, non-reversible, with the steering column at left side. The gear shift and emergency brake lever are at the center. The service brake pedal actuates contracting bands on the external face of, and the emergency brake shoes expand within the drums on the rear wheels. The

Intake Side 4-38 Motor.



Digitized by Google

wheel base is 114 inches; tread, 56 inches; clearance, 10½ inches.

The touring car seats comfortably five passengers. Four full "U" doors all with invisible hinges. Latch handles flush with inside of door. Tonneau equipped with collapsible robe and foot rails. Floor carpeted. Driving compartment covered with linoleum, aluminum trimmed. Pockets located in rear doors. Roomy roadster that will accommodate three average size persons. The rear deck is sloping with door on right side fitted with lock. In the rear of the deck is provided with additional storage space and wide door to permit easy access. The price is $985.

Body Design for a Saxon Chassis.

From E. G. B., New York.—The purpose of this model is for parcel and delivery service. It insures expeditious handling of light merchandise at a low cost. Being equipped with pneumatic tires, the safe delivery of its contents is assured. In this type of car two considerations are of prime importance; the driver's seat must be convenient of access, and the contents of the fore part of the body must be within easy reach of the driver's seat.

Commercial Body and Chassis.

The design shown in the illustration is mounted on a Saxon Six chassis, which has a wheel base of 112 inches, and a tread of 56 inches. The wheels are of artillery type, 32 inches by 3½ inch tires. Users of delivery service admit the advantages of motor propulsion. They are cheaper to operate, cover much territory, take up less room than horses and are of expense only when working.

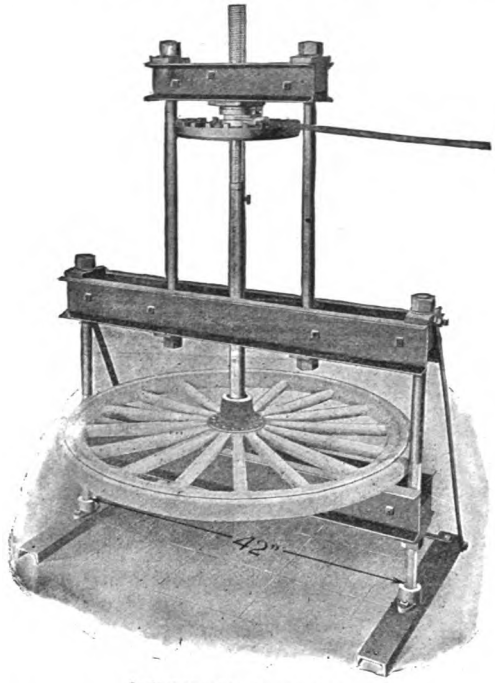
The dimensions of the Saxon Six are as follows: Length, back of driver's seat, 5 feet; width, 4 feet inside; height, 4 feet 6 inches inside; tail board, 1 foot 6 inches. The body has four corner posts 4 feet by 2½ inches by 1¾ inches. Two center posts 4 feet by 2½ inches by 1¾ inches. Seven roof bows ¾ inch by 1¼ inches. Two side sills 5 feet 4 inches. One center sill 5 feet 4 inches, and three cross sills 3 feet 10 inches. The car has a rear drop curtain, and a side curtain for protection for the driver. The seat has a lazy back.

Steering Gear Lost Motion.

In most cars when the steering gear becomes worn and loose it can be adjusted as follows: Jack up the car front so that the wheels can be turned easily, until you feel looseness in the steering gear. Now loosen the three clamping bolts, one of which is at the ring end of the drop arm, the second on the part of the housing which incloses the eccentric bushing carrying the sector, and the third just below the slotted nut on the steering post. Having reached the position in which you can feel the looseness, the slotted nut should be tightened, that is to say turned down, until the play disappears. Then the wheels should be turned as far as possible to one side and the eccentric bushing turned; this brings the sector into closer engagement with the worm. Now the clamping bolts are tightened again. When the effect of this adjustment becomes lost and the small gear or rather sector wears out, the drop arm is removed after the clamping bolt has been taken out, and the steering wheel is given a turn and a half, thereby bringing a different portion of the sector in engagement with the worm. Then the drop arm is replaced, taking care that everything is tightened up properly.

Caught a Guinea Hen.

Mr. and Mrs. Elwyn W. Lovejoy, of Lowell, Mass., met with a curious experience recently. They had been visiting friends in a nearby country town, and were returning about 10 o'clock at night. Without warning something crashed against the wind shield of their car, breaking it and striking the back of the tonneau, just missing the occupants. A fluttering indicated a bird of some sort, which was secured by throwing a robe over it. On reaching home they found a guinea hen. She had probably been attracted by the headlights of the car.



Spots on the body of the car or fenders due to spatters of tar from roadways that have been tar-surfaced, may be removed by washing with soap suds containing a small amount of kerosene oil.

NEW AND INTERESTING THINGS IN MOTORDOM

The Universal Auto Press.

Illustrated herewith will be found a press that will take in every piece of work any garage is called upon to do.

Indispensable in the Garage.

It is quick in action, and its general construction will easily be seen by the illustration. It takes work 42 inches wide and thus has an unusual large capacity. It is useful for strengthening bent axles, for pressing a crankshaft out of a flywheel, and for many other jobs that no other machine will handle. It is made by the United Engine & Mfg. Co., Hanover, Pa.

A Lock for Ford Switch.

A lock that secures the switch and coil-box of a Ford is manufactured by the Stewart Specialty Co., 79 East Chestnut street, Columbus, O. It consists of a hasp-like hinged bar that fastens at the top of the box and, when locked, passes down over the switch and slips over a steel loop at the bottom; a padlock is hooked into the loop and snapped shut, locking up the whole box. The bar is turned up on its hinge when the car is in use.

A Silencer for Ford Cars.

A new and useful accessory for Ford cars has been brought out by the J. W. Saaborn Mfg. Co., of Hampstead, N. H. The manufacturers state that this device absolutely stops all rattle in the spindle arm on Ford cars. It is put in from the front with nippers and when once inserted will stay indefinitely. These silencers cost only 50 cents per pair, and any Ford owner who will try them will be quickly convinced of their merit. Agents are wanted throughout the United States and patents on the device are pending. Correspondence is invited not only from car owners but from supply dealers throughout the country.

Coil Current Adjuster.

A method of adjusting and equalizing the current flow through the coils of a motor ignition system is supplied by the Roberts Instrument Co., 56 Shelby street, Detroit, in its spark coil current indicator, which is simply a specially constructed and calibrated ammeter. Two types are made, one for pocket use and the other for switchboard mounting. The instrument is shunted into the coil circuits one at a time and the coils adjusted until the current consumption is equalized and is as low as is commensurate with the best results. The capacity is 3 amperes.

Reduced Prices for Dort Cars.

The new Dort car now sells for $650 with a complete outfit including electric lighting and starting, one-man top and other essentials. The first car of the present type, which was exhibited at the New York show last January, was listed regularly without the electrical system, but with it as an extra the price was $743. The large volume of business done during the intervening months, coupled with the resulting production economies, however, has justified the substantial reduction. The car in general remains unchanged, barring detail improvements. It is of conventional, light construction, having 105-inch wheelbase and 30x3½-inch Goodyear tires on demountable rims, 50-inch cantilever springs and three-quarter-floating rear axle. The body is a comfortable touring type and it carries speedometer, electric horn and gasoline gauge in addition to the other equipment mentioned. A roadster model, having a smaller motor also is to be produced, which will sell for $540.

A Good Book for Ford Owners.

The Norman W. Hensey Publishing Company, 132 Nassau Street, New York City, has recently published a book entitled "The Model T Ford Car, Its Construction, Operation and Repair." This work is by Victor W. Page. It is cloth bound and contains 300 (5 by 7) pages, and includes over one hundred specially made diagrams and half-tone illustrations, all in correct proportions, and also two large folding plates. This is the most complete and practical instruction book ever published on the Ford car. All parts of the Ford car are described and illustrated in a comprehensive manner and nothing is left for the reader to guess at. The construction is fully treated and the operating principles are made clear. Complete instructions for driving and repairing are given in a non-technical yet thorough manner. The price of the book is $1 and it will be sent by addressing the publishers or the Motor Vehicle Pub. Co., 71 Murray Street, New York.

A New Line of Automobile Accessories.

The Kennedy Mfg. Co., 14 East Jackson Blvd., Chicago, Ill., are making a line of new goods and devices for automobiles, which are unusually attractive. They are made of steel and the finish is so perfect that one might think they were leather. Their bags are no heavier

Standard Kit With Tray.

than leather bags and are built to stand the wear and tear of the hardest use. They make suit cases, trunks and tool kits, as well as other useful articles, which are waterproof and watertight. Anyone interested should address the firm as above.

A New Ford Car Device.

The Badger Automatic Safety Steersman for Ford cars is an insurance against accident, caused by a balky steering wheel. It will keep the car in the road and release the driver from the fatigue of steering. It is sold on a money-back guarantee and is made by the Safety Appliance Co., Baraboo, Wis.

A Garage for $69.50.

The Edwards Mfg. Co., 423-473 Eggleston Ave., Cincinnati, O., make a steel garage 10 x 12 feet, ready to use, which they sell for the unusually low price above mentioned. It is fireproof, portable and quickly set up. A postal card will bring an illustrated catalog containing full information.

A New Garage Air Compressor.

The Brunner Manufacturing Co., Utica, N. Y., are making an unusually good air compressor for garage use. Anything of this sort is indispensable in

Brunner Air Compressor.

a first-class garage, and those interested should send for complete catalog and the name of the nearest agency of the firm.

An Interesting Story.

WHAT'S HE TO ME? By A. A. Hill, Howard O. Bullard, Publisher, 48 New Chambers Street, N. Y. Price, $1.00. This story deals with newspaper and business life, one of the important characters being an editor and publisher, and possibly it may be somewhat auto-biographical. The Brooklyn Eagle says: "It will be read for its spirit as much as for the story itself." The Democratic (N. Y.) Register says: "It is worth reading if only to get acquainted with "Don," "Helen," "Vera," "Rolka," "Mrs. Rolka," and "Uncle Ben," all lovable characters, which drive away all sense of drowsiness on the part of the reader, who does not want to go to sleep while there is a page unread. We thank Mr. Hill for being the means of keeping us awake till the last page was turned over and digested."

An Ideal Headlight.

H. J. Jaeger & Co., Hoboken, N. J., make an automobile headlight which gives an unusually concentrated and uniform light. It is patented and all persons are warned against its manufacture or use, except coming through the patentee. This firm also makes an automobile lamp, which they claim consumes only one-half the amount of electric current that is used in the Tungsten lamps. It has a close focal adjustment and the bulb will not blacken. Dealers or others interested should send for a circular to the address given above, and receive full particulars.

A Ventilated Engine Hood.

There is nothing more conducive to comfort and a cool engine than a ventilated engine hood. Almost every car owner knows this, and yet very few indeed know where to get them. R. G. Ames & Co., 1339 Michigan Avenue, Chicago, make a machine which is guaranteed to ventilate the engine hood in 15 minutes and do it as neatly as if done by the manufacturer before it was painted. It will thus be seen that the cost of the work need not be heavy and yet it will be extremely profitable for the one owning the machine to do it. Garagemen make as high as from $25 to $50 a day ventilating engine hoods, and those who are interested are advised to address the firm as above given for full information and prices.

Tire Lock for Overland Cars.

The New Era Spring & Specialty Co., of Detroit, Mich., are making a lock for tires on the Overland car, which takes the place of the upper strap that holds them. They can be attached easily and quickly and insure tire safety from theft. The price for either the single holder or double holder is low, and there ought to be a wide sale for them.

A Convenient Turntable.

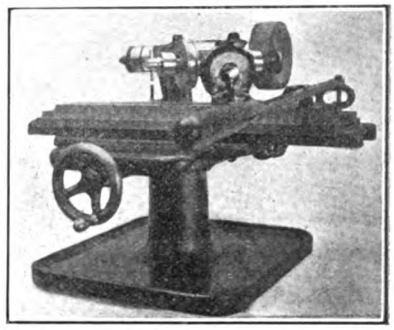
The Rochester Mfg. Co., of Rochester, N. Y., are making a steel turntable with full ball bearings, which may be installed in a few minutes. It is easily operated, and absolutely guaranteed. By addressing the firm as above full particulars may be learned, including the price.

Wheel Rims.

"The trend of automobile rim design is toward simplicity and lightness," says E. R. Hall, of the Goodyear Tire and Rubber Co., Engineering Department.

"This development toward lightness will be hailed with delight by many automobile manufacturers, tending, as it does, to reduce car weight and tire expense. The rims now being placed before the dealers for this year's selling harmonize with the principles sought by many car makers.

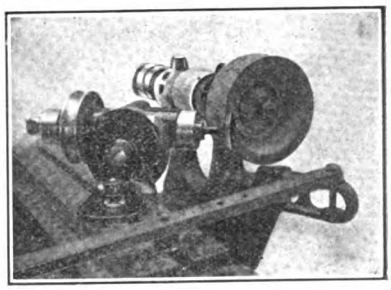
"It is the consensus of opinion among dealers and manufacturers that the transition from the cumbersome to the simplified type, will soon be effected. Our quick detachable rim shows this trend to a high degree. The side ring and the locking flange are combined and can be snapped off the wheel in an instant—and off slips the tire. After the tire is replaced the side flange snaps into place without effort. Following as it does a period of economy tests to determine tire expense, this simplified type comes at a most opportune time. This rim design also gives to rim sales that air of newness that is so essential to a successful selling season.



"With our detachable demountable rim you can not only slip a tire on and off quickly, but you can remove the tire and its rim from the mounting, and replace it with an extra tire on an extra rim. The rim bases of both types are solid—weatherproof and waterproof, eliminating the split that punctures tubes and destroys the trueness of the circumference. Our fastener is designed to wedge the demountable rim on the wheel so tightly that no squeaking can result from the play of the rim on the felloe."

Repair Parts for Ford Cars.

The Grossman Auto Parts Co., of White Plains, N. Y., are selling repair parts for Ford cars, which are guaranteed at greatly reduced prices. They can furnish practically everything that may be required, as well as gears, springs and piston rings for over forty different makes of cars. A complete list of the parts they manufacture will be sent, with prices, to any one who will write for it.



A New Valve Grinder Attachment.

F. E. Wells & Son Co., Greenfield, Mass., have recently brought out a new attachment for their No. 160 or No. 162

F. E Wells & Son Co's Valve Grinder.

"Wells" grinder to be used for re-grinding the valves for Ford engines, although this attachment is also suitable for use in grinding other gasoline engine valves. The illustrations show the grinder set up for grinding the faces of

Set for Grinding Ford Valves.

Ford valves at 45 degree angle. The valve stem is held in a collet and different size collets can be used and supplied for holding various diameters of valve stems.

Magneto Repairs.

The General Magneto Repair Co. announces its removal to 258-260 Halsey street, Newark, N. J., where larger and better accommodations have been secured. They have a full line of special tools, machinery, jigs and repair parts for all lines of magnetos, lighting and starting systems, coils, etc., and are in a position to give better results than you have been receiving in the past and at less cost.

Parts and Accessories.

Illustrated herewith will be found three devices for the automobile among the hundreds if not thousands sold by Stevens & Co., manufacturers of auto and cycle specialties, 375 Broadway, New York. Fig. 1 is a reminder to the driver

Fig. 1.

to resist the frequent temptation to take a chance in a tight place; though, as both sides are alike, it also flashes this hint to the pedestrian. Will fit all radiator caps — also the Ford. Fig. 2 is the Stevens Reserve Valve. Its purpose is to retain one gallon of gasoline in the tank as an emergency supply so that it will be impossible to run dry without warning. It provides convenient shutoff for the gasoline supply to the carburetor while making repairs or in case of fire or accidental leak. The valve is arranged to screw into the tank of any Ford between the tank and the sediment bulb.

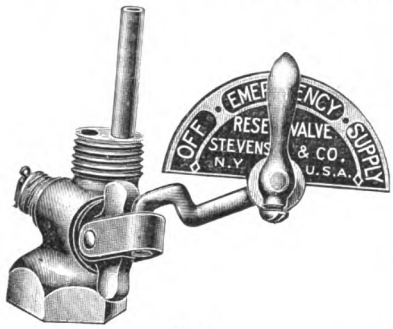

Fig. 2.

Fig. 3 is a Ford Cylinder Tap and Drill Set, for removing broken cylinder

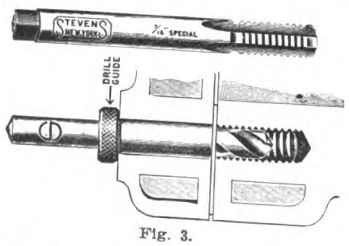

Fig. 3.

head and water connection bolts in Ford cylinders. Ford cylinder head bolts often shear off in an attempt to draw them up too tight and every repairman is familiar with the difficulty of removing the threaded portion that remains in the casting. The operation is simple. A special drill bushing is furnished to guide the drill through the center of the broken bolt so that only a small section of the threads remain. The special tap is then used to clean out the hole leaving it free and ready for a new bolt,—the same size as the original.

Better send for their complete catalogue which illustrates and describes hundreds of unique and valuable devices to make motoring more pleasant and economical.

Carbon Prevented.

A new mineral oil product, manufactured by the Noncarbon Co., 1765 Broadway, New York, has been placed on the market. It is designed to bring about a more complete combustion of the fuel charge in the motor and at the same time prevent the formation of carbon in the cylinders, piston, spark plugs and valve seats. The solution is composed of petroleum products of a solvent and cleansing nature. It is mixed with the gasoline in the proportion of ½ pint to 4 gallons of gasoline and acts with each combustion of the fuel charge. The effect is to cause the carbon to remain in a fine sooty state and it will be blown out with each exhaust of the piston. The manufacturers claim it will not only keep the cylinders free from carbon but will clean them of any deposits that have already been formed.

Used Car Service Coupons.

A marked innovation in the selling of second-hand cars has been inaugurated by Earle C. Anthony, Inc., of Los Angeles, Cal. Henceforth every second-hand car sold by the firm will carry with it a coupon book, good for a certain number of hours of free service labor on the car. The books are identical with those that the concern has been issuing with new Packard and Reo cars sold by it for the past three months, and the coupons are honored not only at the Anthony shop at which the car is purchased, but at every one of the 177 Anthony service stations.

Improvement for the Ford Car.

The Davis-Boyer Co., Detroit, Mich., have anticipated a growing demand for a body equipment for the Ford car chassis. It converts it into a classy roadster and makes it an unusually attractive car. It is not a cheap outfit, but is built substantially and well finished. It will give the best of riding qualities and ample room. It includes not only the body, top and shield but the radiator, starting crank, hood, and in fact everything used above the chassis. It is understood that the price for this outfit is low, considering its high qualities. It really converts the Ford car into something roomy, convenient and in every way desirable.

Ford Car Specialties.

The Peerless Motor Specialty Co., Inc., 136-146 West 52nd Street, New York, are making many exclusive specialties for Ford cars, which they guarantee not only as to quality but price. Among the parts they supply is a coil ignition system, which they claim will give complete freedom from all ignition troubles, an automatic oiling system, shock absorbers, silencers, etc. For prices and their special proposition, please address the firm as above.

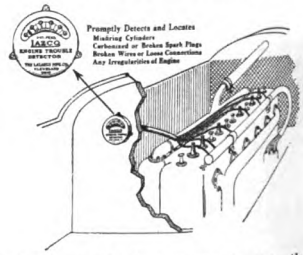
Lighting and Ignition Batteries.

Those who desire batteries of any kind for lighting or ignition should address the General Lead Batteries Co., Chapel Street and Lister Avenue, Newark, N. J. Their TWL type battery is especially recommended for automobile ignition, although where extremely light weight is required the LR types are also offered. Their batteries are designed especially for long life and great efficiency. Thick plates and thick separators are employed to give the highest quality. Six volt sizes are standard but any volt size can be supplied that is desired.

A Brush Carbon Remover.

The Temco Manufacturing Co., of 740 West Van Buren Street, Chicago, make a steel wire brush for removing carbon. It is claimed that it does the work almost instantly and has the appearance of

Temco Carbon Brush.



being in every way desirable for the car owner as well as the garage people. There is an alligator wrench on the handle that will fit any small nut and screwdriver tip for adjusting the points of spark plugs.

An Attractive Display.

The Cox Brass Mfg. Co. of Albany, N. Y., is furnishing its dealers with a more than ordinarily valuable display device, which is strictly in line with modern salesmanship tendencies, in that it not only shows a full size working model of the well known C-C Shock Absorber itself, but displays it as actually attached to the automobile spring. This feature gives it distinct attention value and the display is so arranged that it cannot help to create more than passing interest. This display is only one of the many dealer helps provided by this accessory manufacturer.

A Trouble Detector.

The Lazarus Mfg. Co., of 746 Euclid Avenue, Cleveland, O., are making a device, illustrated herewith, which it is claimed will promply detect and locate misfiring cylinders, carbonized or broken

spark plugs, broken wires or any other irregularities of the engine quickly and surely. The device is not expensive, and the firm will be glad to send particulars to any one writing for them.

Service Gear and Machine Company.

The Service Gear and Machine Company of Reading, Pa., was recently incorporated for $20,000. The company at present is busy manufacturing parts for service stations and parts for jobbers, and makes a specialty of manufacturing transmission gears, bevel gears, axle shafts, piston pins, etc., and maintains a large stock of the above parts for immediate shipment of various makes of cars.

Digitized by Google

New Specialties for Ford Cars.

The Auto Parts Company, Providence, R. I., maker of the Apco line of specialties, which are sold with the guarantee of "Satisfaction or Your Money Back," announces a new specialty for preventing the annoying rattles of the doors on the Ford car. The Apco door anti-rattler consists of a strip of imported spring steel bent at such an

Anti-Rattler.

angle that movement of the door is prevented when closed. The device is attached by using one of the wood screws retaining the body part of the hinge assembly, and the spring can be fitted in less than 30 seconds. It is attached to the bottom of the hinge on the 1915 and 1914 cars and at the top on the 1913 models. It retails for 20 cents and comes black enameled.

A new pedal is now being supplied for the Apco muffler cut-out. It differs from the former in that it is attached to the

Muffler Cut-Out Pedal.

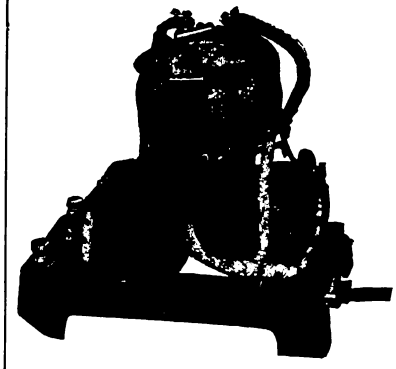
floor board by locking nuts instead of screws, a construction that requires a much smaller hole than the old pedal and one that is very easily installed. The pedal proper is detachable and is secured by a pin.

Perfection Car Heater.

A car heater, which radiates exhaust heat, has been announced by the Perfection-Spring Service Co., Cleveland. By utilizing energy which otherwise is wasted, the heater operates entirely without maintenance cost. A small valve on the exhaust pipe of the car deflects about one-eighth of the hot burnt gases through a flexible steel hose to the heater and then expels it into the open air under the car. The air in the car, circulating around the hot copper tubes of the heater is warmed to a temperature which is entirely comfortable. The Perfection Company declares that in the operation of the heater there is no noise, no odor, no loss of engine power, or back pressure on the motor. The degree of heat is regulated by a simple movement of the driver's foot. The Perfection heater has been successfully used for more than four years. Actual use has shown that even at slow city driving speeds it will heat a seven-passenger touring car with the ordinary loose-fitting side curtains to an agreeable temperature in the coldest weather. The Perfection heater is made in two types, the first of which consists of a series of seamless copper tubes securely assembled into a manifold at each end.

Punctureless Tires.

It is claimed that punctures, rim cuts, blow-outs and all other tire mishaps are avoided by using the French Fibre Model Pacific Tire Treads. These treads are an all-in-one-piece fabric and rubber envelope which covers old casings completely, enveloping them from bead to bead, thereby giving protection at every possible point of contact. The materials from which this tread is compounded are thoroughly tested before entering into Pacific tread construction, and once on an old casing they actually become an integral part of the tire itself, as they will not slip, slide, creep nor sag. Furthermore, the diamond hard steel studs with which this tread is reinforced, in addition to giving a maximum amount of guaranteed mileage, also offer a positive non-skid protection. These treads are made in all sizes, and are adjustable on all kinds of tires, suitable for service on all kinds of rims. Liberal discounts to motorists who are the first to use introductory equipment on their own cars in any given locality. Address V. K. Sturges Co., 26th and Union streets, Oakland, Cal.



Astonishes the Motorist.

In these blase days of motoring, it requires something out of the ordinary to arouse interest in the automobile world. But one of the standard demonstrating stunts of the new spiral gear M. & S. differential is sufficiently uncanny to make the average automobile man wonder how on earth it is done. A Ford car equipped with the M. & S. special type for Fords, is used by the demonstrator. One of the rear wheels is jacked up so that the wheel is entirely off the ground. A two by four is then placed in front of the other three wheels, the engine is started and the driver engages his gear. Imagine the onlookers' surprise, when, instead of seeing the jacked up wheel spin as the power is applied, he sees instead the car move forward over the obstructions and the fourth wheel pulled off the jack. The principle which makes this possible is the arrangement of the spiral gear in the M. & S. differential, whereby power is delivered to the wheel having the greatest traction. A corresponding situation in actual driving occurs in mud, deep sand or on slippery pavements. With the old style bevel gear differential, of course, the wheel that loses traction simply spins—wasting power and wearing out tires. Owing to the number of Ford cars in use, the M. & S. Gear Co. of Detroit has arranged to supply M. & S. differential replacements for the Ford car first. The Ford special type M. & S. is made in the Brown-Lipe-Chapin factory, Syracuse, N. Y.

For Battery Charging.

A new and inexpensive mercury arc rectifier is just being marketed by the General Electric Co., of Schenectady, N. Y., for charging small storage batteries, such as are used for starting, lighting and ignition current in gasoline automobiles and motor boats; for operating electric bells; for electro-plating, and for numerous other uses where not over 5 amperes, 15 volts direct current is required and only alternating current is available. It is designed for charging one 3-cell, one 6-cell or two 3-cell batteries as required, and is automatic. In fact, the rectifier may be connected to a single-cell battery and will charge it at the rate of approximately 6 amperes from 110-volt, a-c. supply. This type of rectifier can be furnished for 60, 50, 40, 30 or 25 cycles, 110-volt circuits. The rectifier is completely self-contained and requires no mechanical ability either to install or operate it. It is so designed that it will maintain a fairly constant

Mercury Arc Rectifier for Charging Small Batteries with Cover Removed.

Method of Starting the Mercury Arc Rectifier for Charging Small Batteries.

current as the voltage of the battery rises. The cost of charging either a 12-volt (6-cell), or two 6-volt (two 3-cell) batteries, for a 10-hour charge, is about 13 cents; or the same for a single 6-volt battery. This cost is based on a rate of 10 cents per k. w. hour for current. Where the rate is less, the charging cost will naturally be proportionately lower.

Disco to Increase Output.

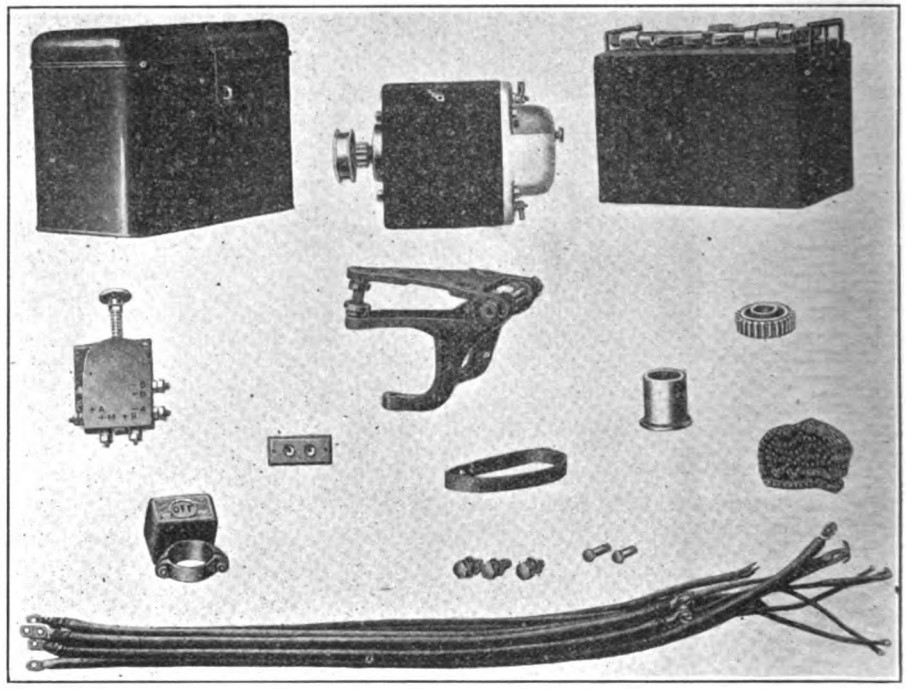
The Disco Electric Starter Co. has taken necessary steps for increasing its output. Additional machinery is to be installed and the working force increased.

Digitized by Google

A Metallic Cable Tire.

Charles E. Miller, Anderson, Ind., is about to place on the market a metallic cable tire which is made on a good deal the same plan as a cotton cord tire, but instead of using cotton cords they use metallic cables, each strand of which is composed of twenty wires, and has a breaking strength of about three hundred pounds, and as they put two layers of these cables into their tires, they get sixteen cables to the inch, making a total of 4,800 pounds tensile strength per inch. These metallic cables extend from one bead to the other, being anchored around the wire in the bead which extends clear around the tire. The tire is built up in the following manner: First on the inside of the tire, where the tube lays, they place a piece of regular tire fabric, over this is placed a sheet of cushion gum, then a layer of metallic cables diagonally across the tire, then another sheet of cushion gum, and on top of this another layer of metallic cables, diagonally across in the opposite direction from the other layer of cables, over this is placed a layer of cushion gum, then a layer of breaker strip extending from bead to bead, then another layer of cushion gum, and another breaker strip extending just over the tread of the tire and on top of this they

Section of the New Tire.

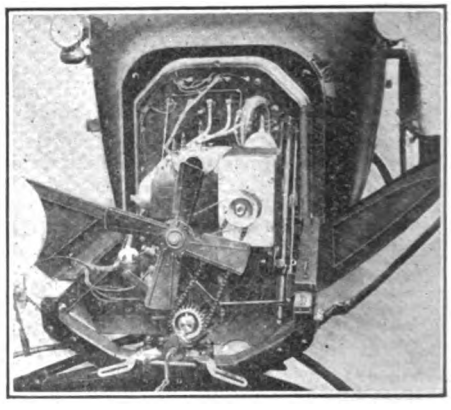


place the tread, which is about one-half inch thick. This makes the tire blow-out proof and almost puncture proof. This tire is very resilient and requires little power to propel it. In traveling at high speed this tire generates less heat than is generated in the ordinary fabric tire. The first cost of the tire will be a little expensive, but in the end it is claimed that you can ride much cheaper on this tire than any yet produced.

For Garage Doors.

A stay designed to hold garage doors open against wind or other forces tending to close them is supplied by the Stanley Works, New Britain, Conn. The stay consists of a jointed angle-steel bar with brackets at each end. One bracket is screwed to the door and the other to the frame, both at the top. When the door is closed the stay is folded upon itself. When the door is opened the stay opens and when the folding joint is straightened out it locks in position, holding the door so it cannot swing either way. To release the door a chain is pulled, throwing the joint off center.

The Dixie 12 Cylinder Magneto.

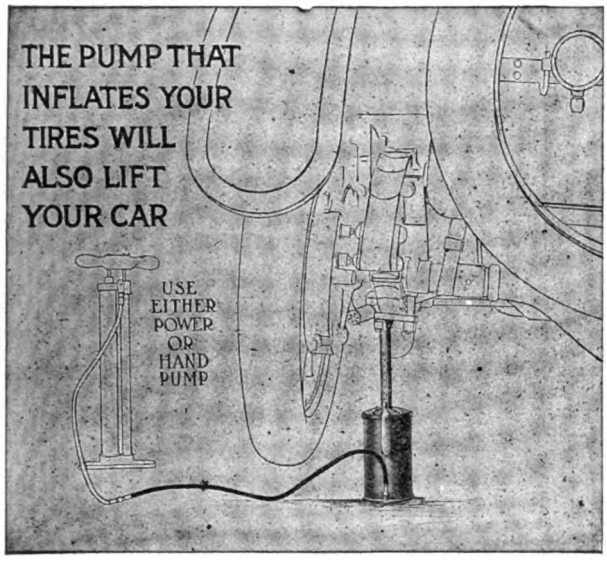


Designers of 12 cylinder engines desire to apply the advantages of magneto ignition to their engines and the advent of the Dixie 12 cylinder magneto makes this possible. The construction of the Dixie 12 follows closely that of the Dixie 4 as used on the Overland. There is no rotating wire wound armature and the usual high tension collector spool with its attendant brushes, so complication is eliminated. The distributor

Splitdorf Apelco Ford Starting and Lighting Parts.

as shown in the illustration is no larger in diameter than the usual 4 cylinder distributor. It has, however, two rows of contacts. Traveling around and wiping over each row of contacts is a separate brush and connected to each one of these brushes is an auxiliary brush so arranged that the high tension current is connected first to one traveling brush and then to the other. At no time are both brushes alive and consequently the separation of the various contacts in the distributor is maintained at such a point that jumping and missfiring is prevented. The two rotating brushes in the distributor carry the same polarity of current and therefore there is no tendency for a breakdown to occur between them. Particular attention is called to the breaker used in the Dixie 12. These contacts operate at 12 cylinder engine speeds in excess of 300 times per second, the vibrations of the breaker arm exceeding in speed the vibration of the middle C string in a piano, in fact, the magneto when running at maximum speed gives a clear musical note. The breaker arms are of special construction carefully balanced and the hammer blow on the platinum points is eliminated by an ingenious arrangement of the various parts. The breaker arm bearing and actuating cam are self-lubricating, the latter having four lobes or bumps, the magneto producing four sparks per revolution. The magneto is geared to the engine 1½ times engine speed and practically any degree of advance and retard is accomplished, the intensity of the spark being the same at either advance or retard for any given engine speed. This feature is unique in the Dixie magneto and is particularly desirable in connection with high speed multi-cylinder engines where excessive spark range is required. In mounting dimensions the Dixie 12 conforms to the S. A. E. standard and in fact is not as large as the conventional four cylinder magneto. Provision is made for cutting out the ignition by means of an ordinary switch connected to a terminal carried on the lid of the breaker box. The accompanying cuts show the external appearance of the machine.

Owing to the fact that the Dixie 12 has no rotating wire wound armature or other parts that would not stand up under excessive speed, the Dixie may be driven at speeds of 5,000 R. P. M. in-



Splitdorf Apelco Ford Starting and Lighting Installation.

definitely, at which speed 20,000 sparks per minute are produced and these are in perfect synchronism and of the same intensity at any given engine speed with the magneto full advance or retard over a spark range, usually of 40 to 60 degrees. It is thought this is a new high record for synchronous spark production which has never been equalled even by battery timers in which of course the spark is variable depending upon the condition of the battery. This magneto is made by the well-known Splitdorf Electrical Co., Newark, N. J.

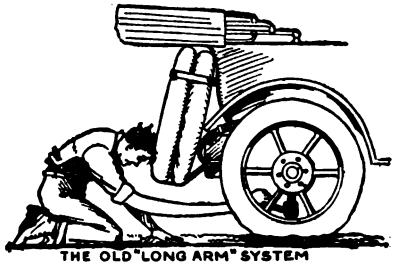
NATIONAL PNEUMATIC JACK

"JUST WHAT I HAVE BEEN LOOKING FOR"

—Is what people are writing us every day

HERE IS A JACK THAT WILL LIFT THE LARGEST CAR WITH NO WORK, NO DIRTY CLOTHES, NO "GETTING DOWN ON ALL FOURS" (like the man in illustration below).

THE "NATIONAL PNEUMATIC JACK" IS AS FAR AHEAD OF THE ORDINARY LEVER JACK AS THE SELF STARTER IS OF THE OLD CRANK.



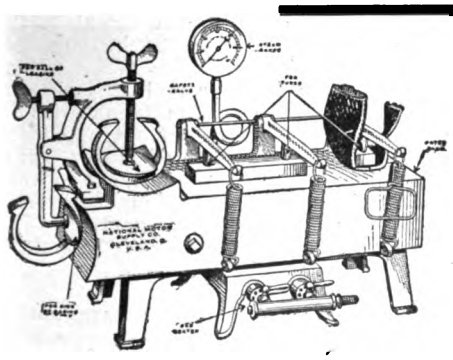
Just slip it under your car, attach either a hand or power pump to the end of hose, and up goes the heaviest car, AND STAYS THERE UNTIL THE AIR IS RELEASED. Has locking device for holding up car in storage. It can't slip. It won't sink in ground on account of its large base. You need not worry about long springs, rear tank, etc., being in the way. Five to ten strokes of ordinary hand pump will lift car. Order one for your old car, or specify that your new car be equipped with it.

Tell the agent he must furnish one with car—and he will.

Ten Days' Free Trial

Will ship one on trial, and if not satisfactory will refund your money. That's fair! Weight only seven pounds. Four inches in diameter, eleven inches high when closed, with six inch lift.

PRICE, by mail prepaid, $6.00



THE OLD "LONG ARM" SYSTEM
IS THIS THE WAY YOU WORK?

Garagemen

This is the jack for you. Just stick on air line hose, raising car instantly, with no slipping, skinned knuckles or hard work. Earns its cost in time saved. Nothing to wear out or get out of order.

Get the agency in your town.

GARAGE AND REPAIR MEN, LOOK!

Thousands of garage men all over the world are making big profits with the

NATIONAL GARAGE STEAM VULCANIZER

Vulcanizes three tubes and two casings at a time. Heated by either gas or gasoline. We have made this machine without any change for six years, which shows how satisfactory it is. You might as well have the big profits for vulcanizing in your vicinity. The National is the easiest and cheapest machine to operate on the market.

LIST PRICE, $60.00

Write for full details and discounts. A card will do.

Prest-O-Lite Cooking Outfit.

The Prest-O-Lite Co., Inc., Indianapolis, Ind., has brought out a compact, convenient cooking outfit, which may be operated from the gas tanks made by this company and which turned on full consumes only about three and one-half feet of gas per hour. The heat of the full flame is said to be sufficient to boil a quart of water in three minutes. The burner plate weighs only six pounds and has tubing attached which may be quickly and easily connected to the acetylene tank.

Carbon Burning Outfit.

F. W. Stewart, 1509 Michigan avenue, Chicago, Ill., has brought out a line of carbon burning outfits, which consists of regulator valves with oxygen tank connections, pressure gauges, expansion chambers, air cocks and nozzles. These outfits may be had with special gauges and burning nozzles, according to the work for which they are required.

Rising Prices for Materials.

Some of the materials that go into the manufacture of automobiles or are used for tools employed in manufacturing processes, have shown an upward price tendency, partly on account of the increasing activities of the automobile industry, but more largely because of the European war. One of the materials most seriously affected is high speed tool steel, which is an alloy steel containing tungsten. In the past a great deal of the high-speed tool steel used in this country has come from England, but at present the local demand for such steel is very great, owing to the war, and very little is being exported. Cyanide of potassium, which is used for case hardening, is also getting scarce, as there is only a single source of this chemical in this country. Burlap, of which large quantities have been imported from Calcutta, is also hard to get, owing to the fact that there are few ships available for transportation.

A Sensation Promised.

R. C. Hupp, president of the Monarch Motor Car Co., Detroit, Mich., promises a veritable sensation with the announcement of the 1916 Monarch, though at the present time he divulges none of the details of the new machine. The announcement is to be made about September 1st.

Cigar Lighter for Fords.

Asch & Co., 1779 Broadway, New York City, have brought out a special cigar lighter for installation on Ford cars which operates direct from the magneto. The lighter tip is designed especially for this purpose and is connected with ten feet of silk cord wire which is led between the dash and footboards, connecting one terminal to the binding post on top of the magneto and the other to any one of the screws which hold the cover on the gear case.

New Wood Wheels for Ford Cars.

The Superior Lamp Mfg. Co., of 136 West 52d street, New York City, has brought out a set of demountable clincher wood wheels for Ford cars. The set consists of four best-growth hickory wheels, with demountable rims attached, including one spare rim, with wrench, and holes drilled, ready to attach. The outfit is furnished in either natural wood or black finish, at the same price. The set lists at $16, with a profitable discount to the trade. Sets are crated conveniently for sample orders, and further information will be gladly furnished upon request. Dealers will do well to investigate.

Micro Piston Rings.

Motorists are satisfied with plain piston rings only because the importance of the rings as an economy and efficiency factor is not generally understood. Elimination of the faults in the Micro ring is accomplished by using two assembled members, a main ring with interfitting stepped joint and a plain-jointed auxiliary ring. The main ring has its outer bearing surface uniformly channeled throughout to receive the snugly fitting auxiliary ring, which also is of larger diameter than the piston, and is of practically the same uniform section as the channel. The outer rim of the auxiliary ring thus forms part of the bearing surface, and by placing the joints of the two rings diametrically opposite, the outer ring seals the opening in the inner ring, and the expansion from opposite points tends to equalize the contact pressure at all points of the cylinder wall. In expanding, the two ring parts act with the flexibility of the leaves of a spring to assure good contact and the absorption of a minimized amount of power in frictional drag and wear. Obviously this design conforms well to a perfect cylinder and holds on a badly worn cylinder. Cars formerly equipped with plain rings and having difficulty in making certain hills on second have been known to make the same hill easily on high, after the installation of Micro rings. The improvement by using a pressure tight ring is also particularly noticeable in starting and at slow speeds.

The Umbarger Fuel Saver and Lubricator.

This desirable accessory is manufactured by the Chandler Sales Co., 9 South Clinton street, Chicago, and they state that it enables car owners to get more mileage, more speed and more power per gallon of gasoline, also that it will give you a smoother running, quicker accelerating and more flexible motor. Local agents are wanted and correspondence is invited.

A Powerful Searchlight.

The Manufacturers Distributing Co., of America, 246 West 56th street, New York, are selling what they call the Nite-Lite, which is an essential accessory of the car. It is invaluable for reading signs, watching the edge of the road, or averting collisions at night, and is indispensable for a trouble light. It is easily and quickly attached and the light can be thrown in any desired direction. Full particulars and price may be had by addressing the firm as above.

Spring Cranker for Ford Cars.

The Cleveland Spring Cranker is [illegible] especially for Ford cars—fitting [illegible] without alteration or machine work. It derives its power from a flat chr[illegible] vanadium steel spring 2½ inches [illegible] and 12 feet long. This spring is c[illegible] up just like a clock spring—one [illegible] being fastened securely to its steel c[illegible] the other end being connected to an [illegible] tension of the crankshaft and wound [illegible] by a pawl and ratchet movement. [illegible] trigger on the dash—right where you [illegible] reach it conveniently, connects [illegible] cranker to the engine and releases [illegible] coil spring. The stored up energy s[illegible] the motor several complete revolutio[illegible] the motor starts, and you are ready [illegible] go. The instant the motor begins [illegible] ning under its own power, the sp[illegible] automatically rewinds and when f[illegible] wound up, the winding mechanism a[illegible] matically ceases to operate. This [illegible] winding takes from twenty to thirty s[illegible] onds according to the speed of the m[illegible] tor. If desired, the cranker is then d[illegible] connected from the engine relieving [illegible] motor of all load and the cranker from all wear.

The manufacturers guarantee each starter for one year against wear or defective material, and, if for any reason it becomes inoperative, will replace it free of cost, providing, however, that the starter has not been tampered with or abused. It is made by The Forest City Electric Co., Cleveland, Ohio.

Four Wheel Chain Drive.

Claude Hoadley, of Gasport, Ind., has built a four-wheel-drive gasoline truck on which he holds U. S. Patent No. 1,020,730. The four-wheel-drive feature as incorporated in this truck employs chain-drive to each of the four wheels, all of which are used for steering. Each axle and jackshaft group is mounted on a fifth wheel device, the same as the front axle of a horse-drawn vehicle, the conventional motor truck steering knuckle not being used. When either axle is turned the complete jackshaft and transmission system turns with it. The motor is carried in front and there is an ingenious system of power transmission from it to the front and rear jackshafts employing four universal joints and bevel and spur gearing. The steering of the front fifth wheel is through a rack and pinion.

Arbenz Car at $675.

The Arbenz Car Co., of Chillicothe, O., has placed on the market a new four-cylinder model which is to sell for $675. It is fitted with a 3¼ x 5 block motor with a removable cylinder head and cooled on the thermo-syphon plan. The transmission elements include a cone clutch, three-speed selective gearset and full-floating rear axle. The wheelbase is 108 inches and tires are 30 x 3½. Equipment includes a one-man top, electric horn, Stewart speedometer and electric lighting and starting apparatus.

Mosler Vesuvius $1.00

Digitized by Google

A Bad Skid against a Curb

might bend this wheel, but it couldn't break it, and even if bent, it could be easily and quickly straightened.

Think what this security means to you.

The Strongest Wheels Made Are

PARKER-HYDRAULIC Pressed Steel Wheels for Ford Cars

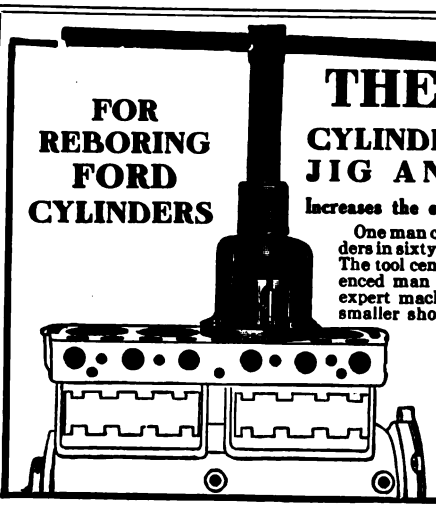
$19.75
SET OF FOUR

enameled black, 30x3½ in. wheels, spare clincher rim, full set of new hub bolts and brace wrench. With wheels enameled red and clincher rims enameled black, $20.50.

And you get this greater strength with half the weight of wooden wheels with demountable rims. This decrease in weight naturally results in a saving in tires.

QUICKER TIRE CHANGES.

These wheels give you the simplest and quickest demountable rims. The only part that comes off is the rim itself. There are no loose parts—nothing to stick—the rim cannot be mounted crooked, and always runs true.



To change a tire simply unscrew each bolt about two turns. This loosens the clips and releases the rim. These wheels have a handsome, baked on, durable finish—are easily cleaned—and **non-rustable.**

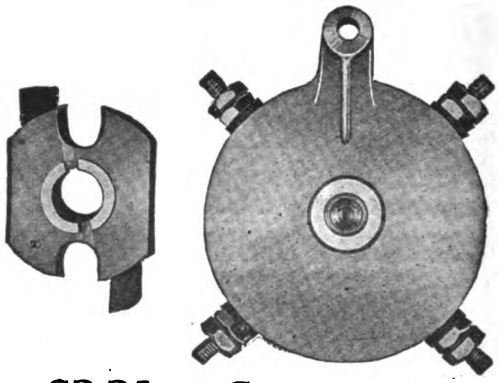
So you see this is the ideal wheel from the standpoints of safety, durability, strength, light weight, attractive finish, and quickness of tire change.

Sold by reliable dealers everywhere. If you don't know yours, write us.

These wheels offer a real opportunity to live dealers. Full details sent on request.

THE HYDRAULIC PRESSED STEEL CO.,
3158 East 61st St., CLEVELAND, O., U. S. A.

FOR REBORING FORD CYLINDERS



THE DAVIS
CYLINDER REBORING JIG AND REAMER

Increases the earning power of your shop

One man can rebore a set of four cylinders in sixty minutes with this machine. The tool centers itself, and an inexperienced man can do as good a job as an expert machinist. With this tool the smaller shops and garages can rebore cylinders and guarantee the work to be as good as the larger dealers with their expensive machinery. Makes the motor better than new. Write for price and full particulars.

The Hinckley Machine Works
Hinckley, Ill.

AT LAST!
A PERFECT TIMER FOR FORD CARS

Price $2.25 **Guaranteed for Life**

With this Timer you get a wipe contact instead of a rolling contact. This contact is made by a low resistance composition brush which makes a positive wipe contact. Furthermore, there is a felt wiper which travels ahead of the brush, which positively keeps contacts clean at all times.

The Rotor in this Timer is in no way affected by centrifugal force, due to the fact that all revolving parts are contained within the rotating unit.

A New Tire Inflator.

The latest Gardner Garage Outfit the "Tire Inflator for Filler Stations," seems to be one of the most popular of the

Gardner Air Compressor.

many Gardner garage outfits. It consists of a Gardner high speed, large capacity compressor connected by belting to an electric motor. A belt tightener being supplied when desired. This mounted upon a strong well seasoned wood frame, which is handsomely finished. A proper size air receiver is held in a horizontal position by the frame. An automatic pressure controlling device is one of the features of the outfit. It regulates the pressure very closely, so that a constant supply of air at the proper pressure is always available. The usual Gardner care is exercised in the design and construction of the outfit. It has a complete equipment of hose, gauges, valves, safety valves, electric connections, fittings, etc. It is made by the Gardner Governor Co., Quincy, Ill.

Easy Ford Steering.

Do you have any trouble steering your Ford car on rough roads? If you do, you should install a Badger Automatic Steersman, which will keep your car as straight as an arrow in the road and relieve you from the strain of driving, to say nothing of the danger of accident. Its cost is a trifle, and it will pay for itself in one long drive. Send to the Safety Appliance Co., Baraboo, Wis., for further particulars. Remember, you get your money back if it is not satisfactory.

For Car Bodies.

The Springfield Commercial Body Co., with an office in the Whitney Building, Springfield, Mass., is putting on the market several new styles of bodies for Ford cars, including the jitney body. Their bodies are said to be unusually well made. The hickory is grown in New England, of the finest stock obtainable, and is beautifully finished. Their prices are unusually low and they carry stocks in several of the large cities in the East for the convenience of patrons. They make almost every description of body for Ford, and likewise Ford demountable rim wheels. They absolutely refuse to sell bodies at retail. Those interested should communicate with the firm as stated.

A Splendid Wrench Set.

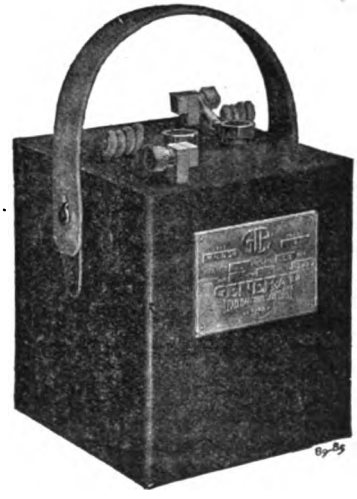
The Walden Mfg. Co., of Worcester, Mass., make a combination Wrench Set with 39 assorted steel sockets and wrenches with 10 end openings. The set also includes a cotter extractor, and several other useful tools. It comes in a strong and well finished fibre box and the price of these tools is very low, considering the wide variety of work for which they are adapted.

Windshield Cleaner.

The Outlook Cleaner Co., Box 124, Cleveland, O., make a windshield cleaner that fits any design of shield and can be attached in two minutes. The price is very low and it is a preventive of danger when driving in rain or a snowstorm.

Perfect Tire Valves.

The firm of A. Schrader's Son, which has been directing most of its efforts for the past 25 years to the turning out of a perfect tire valve, first for bicycles and later for automobiles, announces an important improvement in the packing of its valve-insides. These rather delicate mechanisms, which hitherto had reached the consumer with little or no protection against rough handling or dampness, are now packed in a small tin box just large enough to carry five of the insides. This container, which is both damp-proof and dust-proof, is grooved so that each inside is kept separate from the others. Thus, even when some of the insides have been removed from the box, the others are kept from knocking or rubbing against the rest, thereby insuring each inside reaching the consumer in absolutely perfect condition. The box, which is made to retail at 20 cents, will be especially appreciated by dealers who heretofore have had to handle the Schrader insides in bulk.



One-in-One Piston Ring.

The piston ring is manufactured by the One-In-One Piston Ring Co., Department No. 3, Philadelphia, Pa., and it is guaranteed to give the highest compression and power and to prevent carbon and smoke in the engine. From one to two rings is enough in any piston and the price is so reasonable that anyone can afford them. It is well enough to remember the name and if interested send to the firm for further particulars.

GLB Solve GLB
Ignition Troubles

Dry Batteries are always a source of trouble. The expense of constant renewals at present prices (75% higher than usual) is extravagant when you can buy the T. W. L. Storage Battery, absolutely correct in quality, durability and capacity, for

$8.00 to $10.00 each

With a storage battery on your car you can also have a brilliant light at all times with minimum expense and trouble. The T. W. L. battery will last for years, as it is made up of thick separators and plates with a high ribbed jar.

Write for booklet No. 6.

THE TRIPLEX GAS ECONOMIZER AND CARBON REMOVER

In ordinary operation, air is drawn through holes (2) in tank cover, thence over water (7) and absorbent material (6), through milled slots (4) and automatic valve (11). The holes (10) break up or atomize this moist air so that it readily mixes with the gasoline vapor.

To remove carbon, valve (8) is opened by lifting copper tube (5). This allows water to run from tank directly to combustion chambers where it is converted into live steam which cuts and loosens the accumulated carbon deposit.
